

### Interval Scheduling: Greedy Algorithms

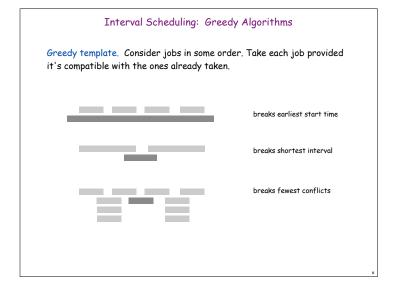

Greedy template. Consider jobs in some order. Take each job provided it's compatible with the ones already taken.

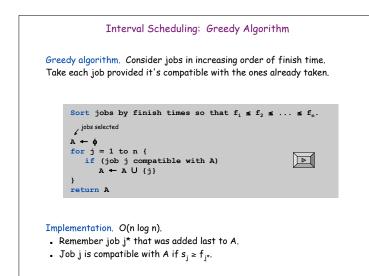

• What order? Does that give best answer? Why or why not? Does it help to be greedy about order?

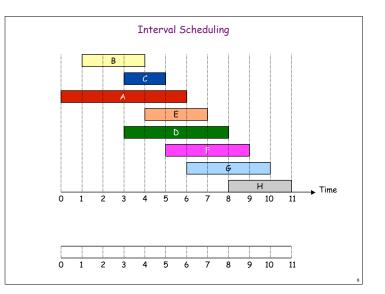

#### Interval Scheduling: Greedy Algorithms

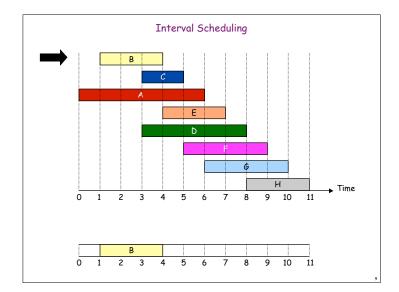

Greedy template. Consider jobs in some order. Take each job provided it's compatible with the ones already taken.

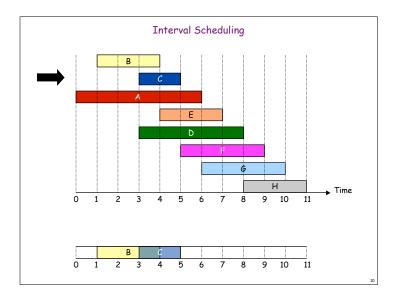

- [Earliest start time] Consider jobs in ascending order of start time  $\boldsymbol{s}_{\rm j}.$
- [Earliest finish time] Consider jobs in ascending order of finish time  $\textbf{f}_{j}.$
- [Shortest interval] Consider jobs in ascending order of interval length  $f_{\rm i}$   $s_{\rm i}.$
- [Fewest conflicts] For each job, count the number of conflicting jobs c<sub>i</sub>. Schedule in ascending order of conflicts c<sub>i</sub>.

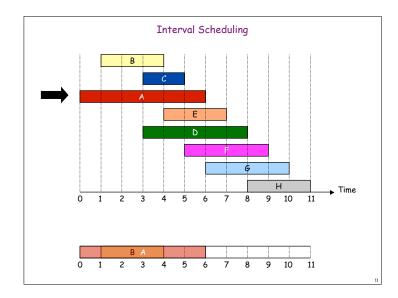

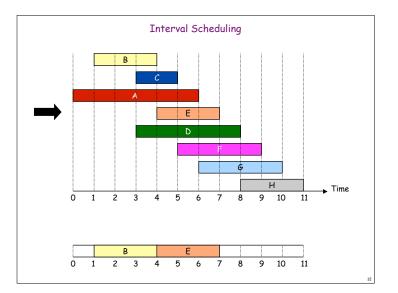

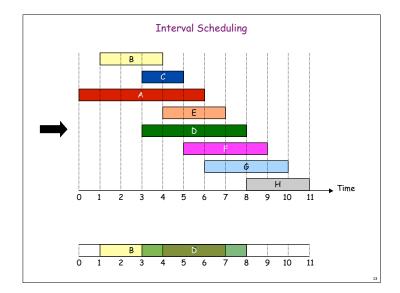

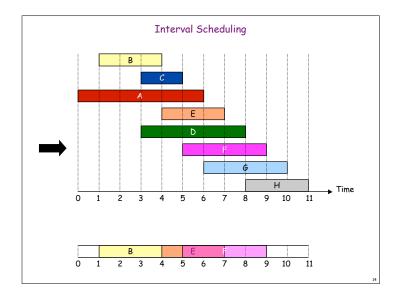

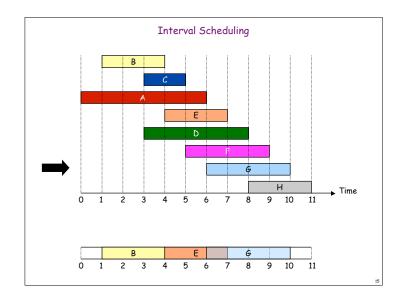

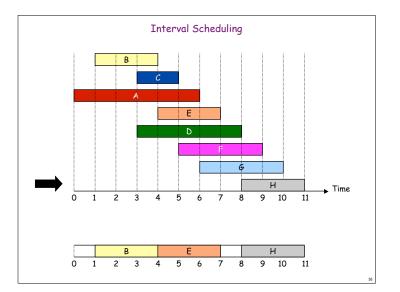

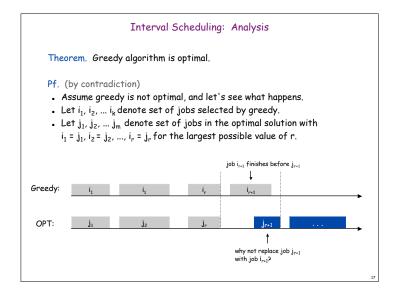

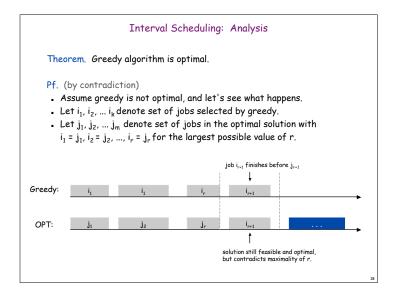

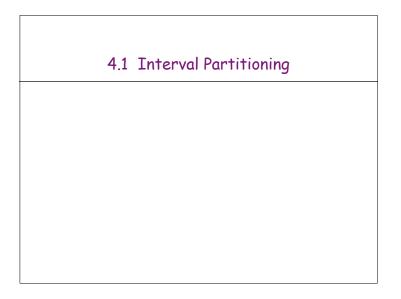

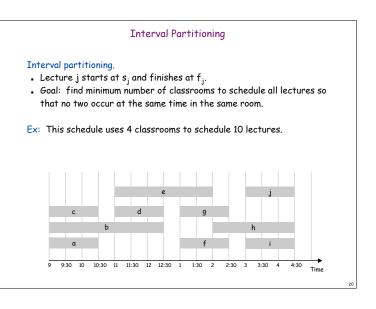

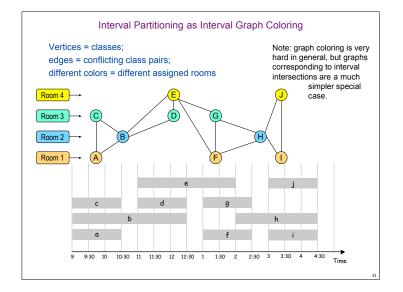

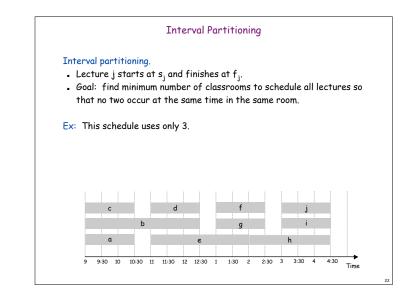

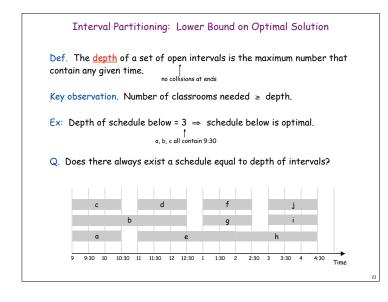

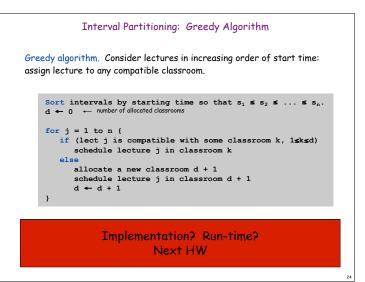

#### Interval Partitioning: Greedy Analysis

Observation. Greedy algorithm never schedules two incompatible lectures in the same classroom.

Theorem. Greedy algorithm is optimal.

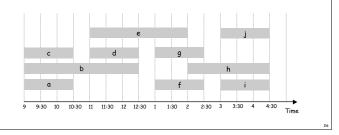

#### Pf.

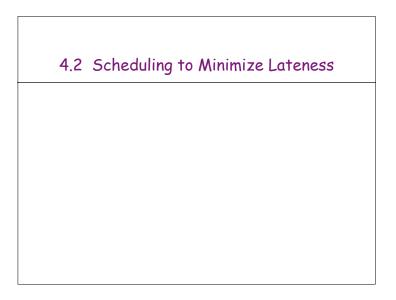

- Let d = number of classrooms that the greedy algorithm allocates.
- Classroom d is opened because we needed to schedule a job, say j, that is incompatible with all d-1 other classrooms.
- Since we sorted by start time, all these incompatibilities are caused by lectures that start no later than s<sub>i</sub>.
- Thus, we have d lectures overlapping at time  $s_i + \varepsilon$ , i.e. depth  $\ge d$
- "Key observation"  $\Rightarrow$  all schedules use  $\ge$  depth classrooms, so d = depth and greedy is optimal =

#### Interval Partitioning: Alt Proof (exchange argument)

When 4th room added, rm 1 was free; why not swap it in there? (A: it conflicts with later stuff in schedule, which dominoes) But: rm 4 schedule after 11:00 is conflict-free; so is rm 1 schedule, so could swap both post-11:00 schedules

Why does it help? Delays needing 4th room; repeat. Cleaner: "Let S\* be an opt sched with latest use of last room; ... swap; ... contradiction"

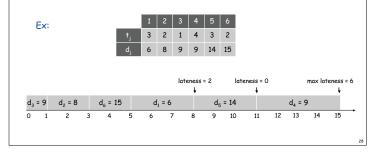

#### Scheduling to Minimizing Lateness

#### Minimizing lateness problem.

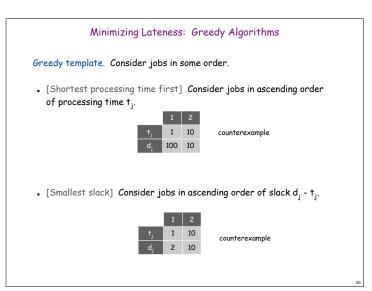

- Single resource processes one job at a time.
- Job j requires t<sub>i</sub> units of processing time and is due at time d<sub>i</sub>.
- If j starts at time  $s_i$ , it finishes at time  $f_i = s_i + t_i$ .
- Lateness:  $\ell_j = \max \{ 0, f_j d_j \}.$
- Goal: schedule all jobs to minimize maximum lateness L = max  $\ell_i$ .

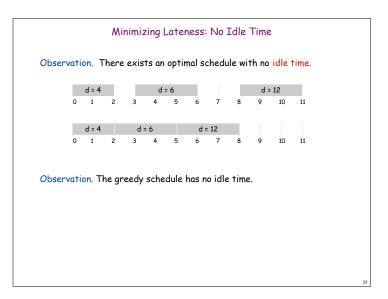

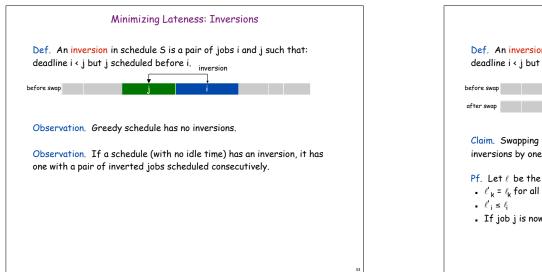

Greedy template. Consider jobs in some order.

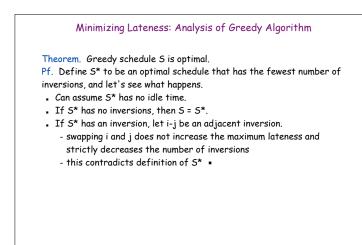

- [Shortest processing time first]
  Consider jobs in ascending order of processing time t<sub>i</sub>.
- [Earliest deadline first]
  Consider jobs in ascending order of deadline d<sub>i</sub>.
- [Smallest slack]
  Consider jobs in ascending order of slack d<sub>j</sub> t<sub>j</sub>.

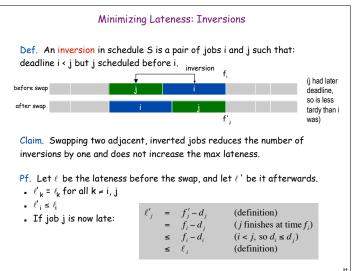

Minimizing Lateness: Greedy	Algorithm
Greedy algorithm. Earliest deadline first.	
Sort n jobs by deadline so that $d_1$ t $\leftarrow 0$ for j = 1 to n Assign job j to interval [t, t $s_j \leftarrow t, f_j \leftarrow t + t_j$ t $\leftarrow t + t_j$ output intervals $[s_j, f_j]$	
1  2  3  4  5  6    t <sub>j</sub> 3  2  1  4  3  2    d <sub>j</sub> 6  8  9  9  14  15	
$\begin{array}{c ccccccccccccccccccccccccccccccccccc$	+
max late	ness = 1

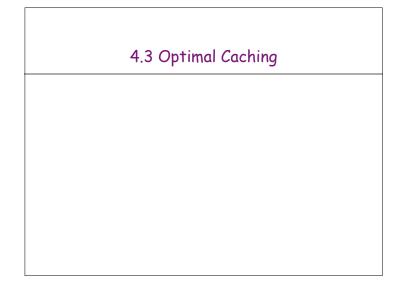

#### Greedy Analysis Strategies

Greedy algorithm stays ahead. Show that after each step of the greedy algorithm, its solution is at least as good as any other algorithm's.

Exchange argument. Gradually transform any solution to the one found by the greedy algorithm without hurting its quality.

Structural. Discover a simple "structural" bound asserting that every possible solution must have a certain value. Then show that your algorithm always achieves this bound.

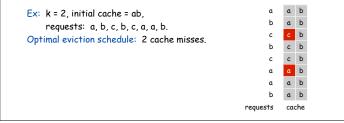

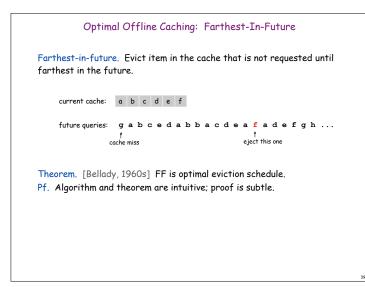

#### **Optimal Offline Caching**

#### Caching.

- Cache with capacity to store k items.
- Sequence of m item requests  $d_1, d_2, ..., d_m$ .
- Cache hit: item already in cache when requested.
- Cache miss: item not already in cache when requested: must bring requested item into cache, and evict some existing item, if full.

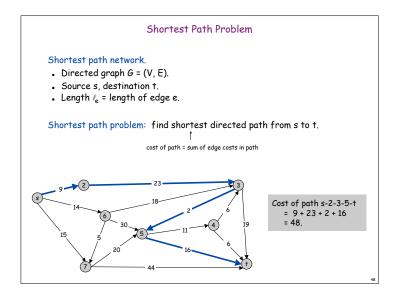

Goal. Eviction schedule that minimizes number of cache misses.

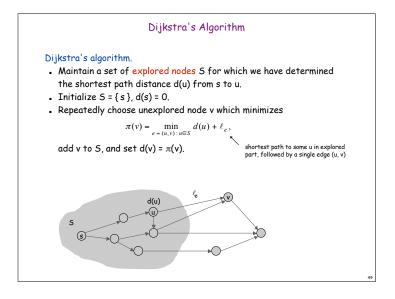

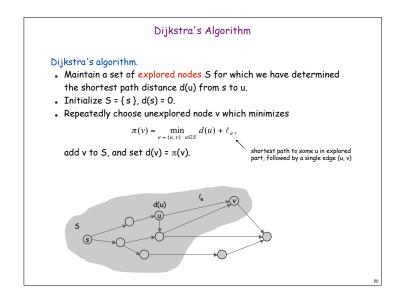

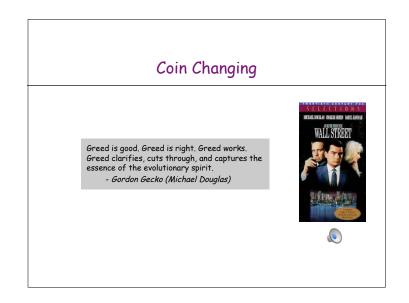

# 4.4 Shortest Paths in a Graph

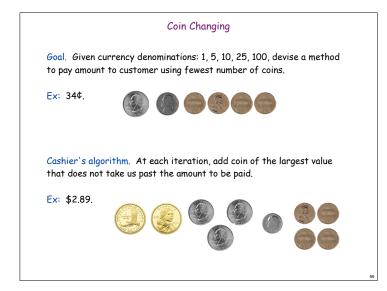

You've seen this in 373, so this section and next two on min spanning tree are review. I won't lecture on them, but you should review the material. Both, but especially shortest paths, are common problems with many applications.

## Coin-Changing: Greedy Algorithm Cashier's algorithm. At each iteration, add coin of the largest value that does not take us past the amount to be paid. Sort coins denominations by value: c<sub>1</sub> < c<sub>2</sub> < ... < c<sub>n</sub>. <sup>coins selected</sup> s ← ∮ while (x ≠ 0) { let k be largest integer such that c<sub>k</sub> ≤ x if (k = 0) return "no solution found" x ← x - c<sub>k</sub> s ← s U {k} } return S

#### Coin-Changing: Analysis of Greedy Algorithm Theorem. Greed is optimal for U.S. coinage: 1, 5, 10, 25, 100. **Pf**. (by induction on x) • Consider optimal way to change $c_k \le x \le c_{k+1}$ : greedy takes coin k. • We claim that any optimal solution must also take coin k. Counterexample. 140¢. - if not, it needs enough coins of type $c_1, ..., c_{k-1}$ to add up to x - table below indicates no optimal solution can do this • Optimal: 70, 70. • Problem reduces to coin-changing x - ck cents, which, by induction, is optimally solved by greedy algorithm. • All optimal solutions Max value of coins must satisfy 1, 2, ..., k-1 in any OPT 1 1 P ≤ 4 \_ 5 4 2 N ≤ 1 3 10 N + D ≤ 2 4 + 5 = 9 4 25 20 + 4 = 24 Q ≤ 3 5 100 no limit 75 + 24 = 99
