

# CSE 417: Algorithms and Computational Complexity

Winter 2009

W. L. Ruzzo

Dynamic Programming, I:  
Fibonacci & Stamps

# Dynamic Programming

## Outline:

General Principles

Easy Examples – Fibonacci, Licking Stamps

Meatier examples

RNA Structure prediction

Weighted interval scheduling

Maybe others

# Some Algorithm Design Techniques, I

## General overall idea

Reduce solving a problem to a smaller problem or problems of the same type

## Greedy algorithms

Used when one needs to build something a piece at a time

Repeatedly make the *greedy* choice - the one that looks the best right away

e.g. closest pair in TSP search

Usually fast if they work (but often don't)

# Some Algorithm Design Techniques, II

## Divide & Conquer

Reduce problem to one or more sub-problems of the same type

Typically, each sub-problem is at most a constant fraction of the size of the original problem

e.g. Mergesort, Binary Search, Strassen's Algorithm, Quicksort  
(kind of)

# Some Algorithm Design Techniques, III

## Dynamic Programming

Give a solution of a problem using smaller sub-problems, e.g. a recursive solution

Useful when the same sub-problems show up again and again in the solution

# “Dynamic Programming”

Program — A plan or procedure for dealing with some matter

– Webster’s New World Dictionary

# Dynamic Programming History

Bellman. Pioneered the systematic study of dynamic programming in the 1950s.

## Etymology.

- Dynamic programming = planning over time.
- Secretary of Defense was hostile to mathematical research.
- Bellman sought an impressive name to avoid confrontation.
  - "it's impossible to use dynamic in a pejorative sense"
  - "something not even a Congressman could object to"

Reference: Bellman, R. E. *Eye of the Hurricane, An Autobiography*.

# A very simple case: Computing Fibonacci Numbers

Recall  $F_n = F_{n-1} + F_{n-2}$  and  $F_0 = 0, F_1 = 1$

Recursive algorithm:

Fibo(n)

if  $n=0$  then return(0)

else if  $n=1$  then return(1)

else return(Fibo(n-1)+Fibo(n-2))

# Call tree - start

# Full call tree

# Memo-ization (Caching)

Save all answers from earlier recursive calls  
Before recursive call, test to see if value has  
already been computed

## Dynamic Programming

*NOT* memoized; instead, convert memoized alg  
from a recursive one to an iterative one  
(top-down → bottom-up)

# Fibonacci - Memoized Version

initialize:  $F[i] \leftarrow$  undefined for all  $i$

$F[0] \leftarrow 0$

$F[1] \leftarrow 1$

FiboMemo( $n$ ):

if( $F[n]$  undefined) {

$F[n] \leftarrow$  FiboMemo( $n-2$ )+FiboMemo( $n-1$ )

}

return( $F[n]$ )

# Fibonacci - Dynamic Programming Version

FiboDP(n):

$F[0] \leftarrow 0$

$F[1] \leftarrow 1$

for  $i=2$  to  $n$  do

$F[i] \leftarrow F[i-1] + F[i-2]$

end

return( $F[n]$ )

For this problem, keeping only last 2 entries instead of full array suffices, but about the same speed

# Dynamic Programming

Useful when

Same recursive sub-problems occur *repeatedly*

Parameters of these recursive calls anticipated

The solution to whole problem can be solved without knowing the *internal* details of how the sub-problems are solved

“principle of optimality”

# Making change

Given:

Large supply of 1¢, 5¢, 10¢, 25¢, 50¢ coins

An amount  $N$

Problem: choose fewest coins totaling  $N$

Cashier's (greedy) algorithm works:

Give as many as possible of the next biggest denomination

# Licking Stamps

Given:

Large supply of 5¢, 4¢, and 1¢ stamps

An amount  $N$

Problem: choose fewest stamps totaling  $N$

# How to Lick 27¢

# of 5¢ stamps	# of 4 ¢ stamps	# of 1¢ stamps	total number
5	0	2	7
4	1	3	8
3	3	0	6

Morals: Greed doesn't pay; success of "cashier's alg" depends on coin denominations

# A Simple Algorithm

At most  $N$  stamps needed, etc.

```
for a = 0, ..., N {  
  for b = 0, ..., N {  
    for c = 0, ..., N {  
      if (5a+4b+c == N && a+b+c is new min)  
        {retain (a,b,c);}}}  
output retained triple;
```

Time:  $O(N^3)$

(Not too hard to see some optimizations, but we're after bigger fish...)

## Better Idea

Theorem: If last stamp in an opt sol has value  $v$ , then previous stamps are opt sol for  $N-v$ .

Proof: if not, we could improve the solution for  $N$  by using opt for  $N-v$ .

Alg: for  $i = 1$  to  $n$ :

$$M(i) = \min \left\{ \begin{array}{ll} 0 & i=0 \\ 1+M(i-5) & i \geq 5 \\ 1+M(i-4) & i \geq 4 \\ 1+M(i-1) & i \geq 1 \end{array} \right\}$$

where  $M(i)$  = min number of stamps totaling  $i\text{¢}$

# New Idea: Recursion

$$M(i) = \min \begin{cases} 0 & i=0 \\ 1+M(i-5) & i \geq 5 \\ 1+M(i-4) & i \geq 4 \\ 1+M(i-1) & i \geq 1 \end{cases}$$

Time:  $> 3^{N/5}$

# Another New Idea: Avoid Recomputation

Tabulate values of solved subproblems

Top-down: “memoization”

Bottom up:

$$\text{for } i = 0, \dots, N \text{ do } M[i] = \min \left\{ \begin{array}{ll} 0 & i=0 \\ 1+M[i-5] & i \geq 5 \\ 1+M[i-4] & i \geq 4 \\ 1+M[i-1] & i \geq 1 \end{array} \right\}$$

Time:  $O(N)$

# Finding *How Many Stamps*

i	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14
M(i)	0	1	2	3	1	1	2	3	2						

$$1 + \text{Min}(3, 1, 3) = 2$$

# Finding *Which* Stamps: Trace-Back

i	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14
M(i)	0	1	2	3	1	1	2	3	2						

1 + Min(3, 1, 3) = 2

# Trace-Back

## Way 1: tabulate all

add data structure storing back-pointers indicating which predecessor gave the min. (more space, maybe less time)

## Way 2: re-compute just what's needed

```
TraceBack(i):  
    if i == 0 then return;  
    for d in {1, 4, 5} do  
        if M[i] == 1 + M[i - d]  
            then break;  
    print d;  
    TraceBack(i - d);
```

$$M[i] = \min \left\{ \begin{array}{ll} 0 & i=0 \\ 1+M[i-5] & i \geq 5 \\ 1+M[i-4] & i \geq 4 \\ 1+M[i-1] & i \geq 1 \end{array} \right.$$

# Complexity Note

$O(N)$  is better than  $O(N^3)$  or  $O(3^{N/5})$

But still *exponential* in input size  
(log N bits)

(E.g., miserable if N is 64 bits –  $c \cdot 2^{64}$  steps &  $2^{64}$  memory.)

Note: can do in  $O(1)$  for 5¢, 4¢, and 1¢ but not in general. See “NP-Completeness” later.

# Elements of Dynamic Programming

What feature did we use?

What should we look for to use again?

## “Optimal Substructure”

Optimal solution contains optimal subproblems

A non-example:  $\min(\text{number of stamps mod } 2)$

## “Repeated Subproblems”

The same subproblems arise in various ways
