Algorithms

Huffman Codes:
An Optimal Data Compression
Method

Compression Example

100k file, 6 letter alphabet:

File Size:

ASCII, 8 bits/char: 800kbits

$2^3 > 6$; 3 bits/char: 300kbits

a	45%
b	13%
c	12%
d	16%
e	9%
f	5%

Why?

Storage, transmission vs 5 Ghz cpu

Compression Example

100k file, 6 letter alphabet:

a	45%
b	13%
c	12%
d	16%
e	9%
f	5%

File Size:

ASCII, 8 bits/char: 800kbits

$2^3 > 6$; 3 bits/char: 300kbits

better: \longrightarrow

2.52 bits/char $74\%*2 + 26\%*4$: 252kbits

Optimal?

	E.g.:	Why not:
a	00	00
b	01	01
d	10	10
c	1100	110
e	1101	1101
f	1110	1110

1101110 = cf or ec? ₃

Data Compression

Binary character code (“code”)

each k -bit *source string* maps to unique *code word*
(e.g. $k=8$)

“compression” alg: concatenate code words for
successive k -bit “characters” of source

Fixed/variable length codes

all code words equal length?

Prefix codes

no code word is prefix of another (unique decoding)

Prefix Codes = Trees

a	45%
b	13%
c	12%
d	16%
e	9%
f	5%

1 0 1 0 0 0 0 0 1
 f a b

1 1 0 0 0 1 0 1
 f a b

Greedy Idea #1

a	45%
b	13%
c	12%
d	16%
e	9%
f	5%

Put most frequent
under root, then recurse ...

Greedy Idea #1

Top down: Put *most* frequent under root, then recurse

**Too greedy:
unbalanced tree**

$$.45*1 + .16*2 + .13*3 \dots = 2.34$$

not too bad, but imagine if all freqs were $\sim 1/6$:

$$(1+2+3+4+5+5)/6=3.33$$

a	45%
b	13%
c	12%
d	16%
e	9%
f	5%

Greedy Idea #2

a	45%
b	13%
c	12%
d	16%
e	9%
f	5%

Top down: Divide letters into 2 groups, with ~50% weight in each; recurse (Shannon-Fano code)

Again, not terrible

$$2 \cdot .5 + 3 \cdot .5 = 2.5$$

But this tree can easily be improved! (How?)

Greedy idea #3

a	45%
b	13%
c	12%
d	16%
e	9%
f	5%

Bottom up: Group
least frequent letters
near bottom

$.45 \cdot 1 + .41 \cdot 3 + .14 \cdot 4 = 2.24$ bits per char

Huffman's Algorithm (1952)

Algorithm:

insert node for each letter into priority queue by freq

while queue length > 1 do

 remove smallest 2; call them x, y

 make new node z from them, with $f(z) = f(x) + f(y)$

 insert z into queue

Analysis: $O(n)$ heap ops: $O(n \log n)$

Goal: Minimize $B(T) = \sum_{c \in C} \text{freq}(c) * \text{depth}(c)$

T = Tree
C = alphabet

Correctness: ???

Correctness Strategy

Optimal solution may not be **unique**, so cannot prove that greedy gives the *only* possible answer.

Instead, show that greedy's solution is **as good as any**.

How: an exchange argument

Defn: A pair of leaves x, y is an inversion if

$$\text{depth}(x) \geq \text{depth}(y)$$

and

$$\text{freq}(x) \geq \text{freq}(y)$$

Claim: If we flip an inversion, cost never increases.

Why? All other things being equal, better to give more frequent letter the shorter code.

$$\begin{aligned} & \text{before} & \text{after} \\ & \underbrace{\hspace{10em}} & \underbrace{\hspace{10em}} \\ & (d(x)*f(x) + d(y)*f(y)) - (d(x)*f(y) + d(y)*f(x)) = \\ & (d(x) - d(y)) * (f(x) - f(y)) \geq 0 \end{aligned}$$

I.e., non-negative cost savings.

Lemma I: “Greedy Choice Property”

The 2 least frequent letters might
as well be siblings

Let a be least freq, b 2nd

Let u, v be siblings at
max depth, $f(u) \leq f(v)$
(why must they exist?)

Then (a,u) and (b,v) are
inversions. Swap them.

Why Important? Algorithm is not wrong to join them.

Lemma 2

Let (C, f) be a problem instance: C an n -letter alphabet with letter frequencies $f(c)$ for c in C .

For any x, y in C , z not in C , let C' be the $(n-1)$ letter alphabet $C - \{x,y\} \cup \{z\}$ and for all c in C' define

$$f'(c) = \begin{cases} f(c), & \text{if } c \neq x,y,z \\ f(x) + f(y), & \text{if } c = z \end{cases}$$

Let T' be an optimal tree for (C', f') .

Then

is optimal for (C, f) among all trees having x, y as siblings

Why Important? Algorithm is not wrong to treat $x:y$ as z .

Proof:

$$B(T) = \sum_{c \in C} d_T(c) \cdot f(c)$$

$$\begin{aligned} B(T) - B(T') &= d_T(x) \cdot (f(x) + f(y)) - d_{T'}(z) \cdot f'(z) \\ &= (d_{T'}(z) + 1) \cdot f'(z) - d_{T'}(z) \cdot f'(z) \\ &= f'(z) \end{aligned}$$

Suppose \hat{T} (having x & y as siblings) is better than T , i.e.

$B(\hat{T}) < B(T)$. Collapse x & y to z , forming \hat{T}' ; as above:

$$B(\hat{T}) - B(\hat{T}') = f'(z)$$

Then:

$$B(\hat{T}') = B(\hat{T}) - f'(z) < B(T) - f'(z) = B(T')$$

Contradicting optimality of T'

Theorem:

Huffman gives optimal codes

Proof: induction on $|C|$

Basis: $n=1,2$ – immediate

Induction: $n>2$

Let x,y be least frequent

Form $C', f',$ & z , as above

By induction, T' is opt for (C',f')

By lemma 2, $T' \rightarrow T$ is opt for (C,f) among trees
with x,y as siblings

By lemma 1, some opt tree has x, y as siblings

Therefore, T is optimal.

Data Compression

Huffman is **optimal**.

BUT still might do better!

Huffman encodes fixed length blocks. What if we vary them?

Huffman uses one encoding throughout a file. What if characteristics change?

What if data has structure? E.g. raster images, video,...

Huffman is lossless. Necessary?

LZW, MPEG, ...

David A. Huffman, 1925-1999
