

## CSE 421 Algorithms

Richard Anderson  
Lecture 20  
Space Efficient LCS

## Longest Common Subsequence

- $C=c_1\dots c_g$  is a subsequence of  $A=a_1\dots a_m$  if  $C$  can be obtained by removing elements from  $A$  (but retaining order)
- $LCS(A, B)$ : A maximum length sequence that is a subsequence of both  $A$  and  $B$
- Wednesday's Result:
  - $O(mn)$  time,  $O(mn)$  space LCS Algorithm
- Today's Result:
  - $O(mn)$  time,  $O(m+n)$  space LCS Algorithm

## Digression: String Alignment Problem

- Align sequences with gaps  
 $CAT\ TGA\ AT$   
 $CAGAT\ AGGA$
- Charge  $\delta_x$  if character  $x$  is unmatched
- Charge  $\gamma_{xy}$  if character  $x$  is matched to character  $y$
- Find alignment to minimize sum of costs

## Optimization Recurrence for the String Alignment Problem

- Charge  $\delta_x$  if character  $x$  is unmatched
- Charge  $\gamma_{xy}$  if character  $x$  is matched to character  $y$
- $A = a_1a_2\dots a_m$ ;  $B = b_1b_2\dots b_n$
- $Opt[j, k]$  is the value of the minimum cost alignment  $a_1a_2\dots a_j$  and  $b_1b_2\dots b_k$

## Dynamic Programming Computation

## Storing the path information

```

A[1..m], B[1..n]
for i := 1 to m  Opt[i, 0] := 0;
for j := 1 to n  Opt[0, j] := 0;
Opt[0, 0] := 0;
for i := 1 to m
  for j := 1 to n
    if A[i] = B[j] { Opt[i, j] := 1 + Opt[i-1, j-1]; Best[i, j] := Diag; }
    else if Opt[i-1, j] >= Opt[i, j-1]
      { Opt[i, j] := Opt[i-1, j]; Best[i, j] := Left; }
    else { Opt[i, j] := Opt[i, j-1]; Best[i, j] := Down; }

```

### Observations about the Algorithm

- The computation can be done in  $O(m+n)$  space if we only need one column of the Opt values or Best Values
- The algorithm can be run from either end of the strings

### Divide and Conquer Algorithm

- Where does the best path cross the middle column?

- For a fixed  $i$ , and for each  $j$ , compute the LCS that has  $a_i$  matched with  $b_j$

### Constrained LCS

- $LCS_{i,j}(A,B)$ : The LCS such that
  - $a_1, \dots, a_i$  paired with elements of  $b_1, \dots, b_j$
  - $a_{i+1}, \dots, a_m$  paired with elements of  $b_{j+1}, \dots, b_n$
- $LCS_{4,3}(abbacbb, cbbaa)$

A = **RRSSRTTRTS**  
B = **RTSRRSTST**

Compute  $LCS_{5,0}(A,B)$ ,  $LCS_{5,1}(A,B)$ ,  $LCS_{5,2}(A,B)$ , ...,  $LCS_{5,9}(A,B)$

A = **RRSSRTTRTS**  
B = **RTSRRSTST**

Compute  $LCS_{5,0}(A,B)$ ,  $LCS_{5,1}(A,B)$ ,  $LCS_{5,2}(A,B)$ , ...,  $LCS_{5,9}(A,B)$

j	left	right
0	0	3
1	1	3
2	1	3
3	2	3
4	3	3
5	3	2
6	3	2
7	3	1
8	4	1
9	4	0

### Computing the middle column

- From the left, compute  $LCS(a_1 \dots a_{m/2}, b_1 \dots b_j)$
- From the right, compute  $LCS(a_{m/2+1} \dots a_m, b_{j+1} \dots b_n)$
- Add values for corresponding  $j$ 's

- Note – this is space efficient

## Divide and Conquer

- $A = a_1, \dots, a_m$        $B = b_1, \dots, b_n$
- Find  $j$  such that
  - $\text{LCS}(a_1 \dots a_{m/2}, b_1 \dots b_j)$  and
  - $\text{LCS}(a_{m/2+1} \dots a_m, b_{j+1} \dots b_n)$  yield optimal solution
- Recurse

## Algorithm Analysis

- $T(m,n) = T(m/2, j) + T(m/2, n-j) + cnm$

Prove by induction that  
 $T(m,n) \leq 2cmn$

## Shortest Path Problem

- Dijkstra's Single Source Shortest Paths Algorithm
  - $O(m \log n)$  time, positive cost edges
- General case – handling negative edges
- If there exists a negative cost cycle, the shortest path is not defined
- Bellman-Ford Algorithm
  - $O(mn)$  time for graphs with negative cost edges

## Lemma

- If a graph has no negative cost cycles, then the **shortest** paths are **simple** paths
- Shortest paths have at most  $n-1$  edges

## Shortest paths with a fixed number of edges

- Find the shortest path from  $v$  to  $w$  with exactly  $k$  edges

## Express as a recurrence

- $Opt_k(w) = \min_x [Opt_{k-1}(x) + c_{xw}]$
- $Opt_0(w) = 0$  if  $v=w$  and infinity otherwise

## Algorithm, Version 1

```

foreach w
    M[0, w] = infinity;
M[0, v] = 0;
for i = 1 to n-1
    foreach w
        M[i, w] = min_x(M[i-1, x] + cost[x, w]);
    
```

## Algorithm, Version 2

```

foreach w
    M[0, w] = infinity;
M[0, v] = 0;
for i = 1 to n-1
    foreach w
        M[i, w] = min(M[i-1, w], min_x(M[i-1, x] + cost[x, w]));
    
```

## Algorithm, Version 3

```

foreach w
    M[w] = infinity;
M[v] = 0;
for i = 1 to n-1
    foreach w
        M[w] = min(M[w], min_x(M[x] + cost[x, w]));
    
```

## Correctness Proof for Algorithm 3

- Key lemma – at the end of iteration  $i$ , for all  $w$ ,  $M[w] \leq M[i, w]$ ;
- Reconstructing the path:
  - Set  $P[w] = x$ , whenever  $M[w]$  is updated from vertex  $x$

## If the pointer graph has a cycle, then the graph has a negative cost cycle

- If  $P[w] = x$  then  $M[w] \geq M[x] + \text{cost}(x, w)$ 
  - Equal after update, then  $M[x]$  could be reduced
- Let  $v_1, v_2, \dots, v_k$  be a cycle in the pointer graph with  $(v_k, v_1)$  the last edge added
  - Just before the update
    - $M[v_j] \geq M[v_{j+1}] + \text{cost}(v_{j+1}, v_j)$  for  $j < k$
    - $M[v_k] > M[v_1] + \text{cost}(v_1, v_k)$
  - Adding everything up
    - $0 > \text{cost}(v_1, v_2) + \text{cost}(v_2, v_3) + \dots + \text{cost}(v_k, v_1)$

## Negative Cycles

- If the pointer graph has a cycle, then the graph has a negative cycle
- Therefore: if the graph has no negative cycles, then the pointer graph has no negative cycles

## Finding negative cost cycles

- What if you want to find negative cost cycles?
