

# CSE 421 Algorithms

Richard Anderson  
Lecture 17  
Dynamic Programming

## Dynamic Programming

- Weighted Interval Scheduling
- Given a collection of intervals  $I_1, \dots, I_n$  with weights  $w_1, \dots, w_n$ , choose a maximum weight set of non-overlapping intervals

## Optimality Condition

- $Opt[j]$  is the maximum weight independent set of intervals  $I_1, I_2, \dots, I_j$
- $Opt[j] = \max(Opt[j-1], w_j + Opt[p[j]])$ 
  - Where  $p[j]$  is the index of the last interval which finishes before  $I_j$  starts

## Algorithm

```
MaxValue(j) =  
  if j = 0 return 0  
  else  
    return max( MaxValue(j-1),  
               w_j + MaxValue(p[j]) )
```

Worst case run time:  $2^n$

## A better algorithm

$M[j]$  initialized to -1 before the first recursive call for all  $j$

```
MaxValue(j) =  
  if j = 0 return 0;  
  else if  $M[j] \neq -1$  return  $M[j]$ ;  
  else  
     $M[j] = \max(\text{MaxValue}(j-1), w_j + \text{MaxValue}(p[j]))$ ;  
    return  $M[j]$ ;
```

## Iterative Algorithm

Express the MaxValue algorithm as an iterative algorithm

```
MaxValue {  
  
  
  
  
  
  
  
  
  
}
```

Fill in the array with the Opt values

$$\text{Opt}[j] = \max(\text{Opt}[j - 1], w_j + \text{Opt}[p[j]])$$

Computing the solution

$$\text{Opt}[j] = \max(\text{Opt}[j - 1], w_j + \text{Opt}[p[j]])$$

Record which case is used in Opt computation

## Dynamic Programming

- The most important algorithmic technique covered in CSE 421
- Key ideas
  - Express solution in terms of a polynomial number of sub problems
  - Order sub problems to avoid recomputation

## Optimal linear interpolation

What is the optimal linear interpolation with three line segments

What is the optimal linear interpolation with two line segments

## What is the optimal linear interpolation with n line segments

## Notation

- Points  $p_1, p_2, \dots, p_n$  ordered by x-coordinate ( $p_i = (x_i, y_i)$ )
- $E_{i,j}$  is the least squares error for the optimal line interpolating  $p_i, \dots, p_j$

## Optimal interpolation with two segments

- Give an equation for the optimal interpolation of  $p_1, \dots, p_n$  with two line segments
- $E_{i,j}$  is the least squares error for the optimal line interpolating  $p_i, \dots, p_j$

## Optimal interpolation with k segments

- Optimal segmentation with three segments
  - $\text{Min}_{i,j} \{E_{1,i} + E_{i,j} + E_{j,n}\}$
  - $O(n^2)$  combinations considered
- Generalization to k segments leads to considering  $O(n^{k-1})$  combinations

$\text{Opt}_k[j]$  : Minimum error approximating  $p_1 \dots p_j$  with k segments

How do you express  $\text{Opt}_k[j]$  in terms of  $\text{Opt}_{k-1}[1], \dots, \text{Opt}_{k-1}[j]$ ?

## Optimal sub-solution property

Optimal solution with k segments extends an optimal solution of k-1 segments on a smaller problem

## Optimal multi-segment interpolation

Compute  $\text{Opt}[k, j]$  for  $0 < k < j < n$

for  $j := 1$  to  $n$

$\text{Opt}[1, j] = E_{1,j}$ ;

for  $k := 2$  to  $n-1$

    for  $j := 2$  to  $n$

$t := E_{1,j}$

        for  $i := 1$  to  $j-1$

$t = \min(t, \text{Opt}[k-1, i] + E_{i,j})$

$\text{Opt}[k, j] = t$

## Determining the solution

- When  $\text{Opt}[k,j]$  is computed, record the value of  $i$  that minimized the sum
- Store this value in a auxiliary array
- Use to reconstruct solution

## Variable number of segments

- Segments not specified in advance
- Penalty function associated with segments
- Cost = Interpolation error +  $C \times \text{\#Segments}$

## Penalty cost measure

- $\text{Opt}[j] = \min(E_{1,j}, \min_i(\text{Opt}[i] + E_{i,j} + P))$
