Depth First Search

Yin Tat Lee

Summary of last lecture

- **BFS(s)** implemented using queue.
- Edges into then-undiscovered vertices define a tree – the “Breadth First spanning tree” of G
- Level i in the tree are exactly all vertices v s.t., the shortest path (in G) from the root s to v is of length i
- **All** nontree edges join vertices on the same or adjacent levels of the tree
- Applications:
 - Shortest Path
 - Connected component
 - Test bipartiteness / 2-coloring

Preview of this lecture

- Depth First Search
- 1 property: non-tree edge is vertical instead of horizontal
- 1 application: topological sort

Depth First Search

Follow the first path you find as far as you can go; back up to last unexplored edge when you reach a dead end, then go as far you can

Naturally implemented using recursive calls or a stack

DFS(s) – Recursive version

Initialization: mark all vertices undiscovered

DFS(v)

Mark v discovered

for each edge $\{v, x\}$

if (x is undiscovered)

Mark x discovered

DFS(x)

Mark v fully-discovered

Non-Tree Edges in DFS

BFS tree \neq DFS tree, but, as with BFS, DFS has found a tree in the graph s.t. non-tree edges are "simple" in some way.

All non-tree edges join a vertex and one of its descendants/ancestors in the DFS tree

DFS(A)

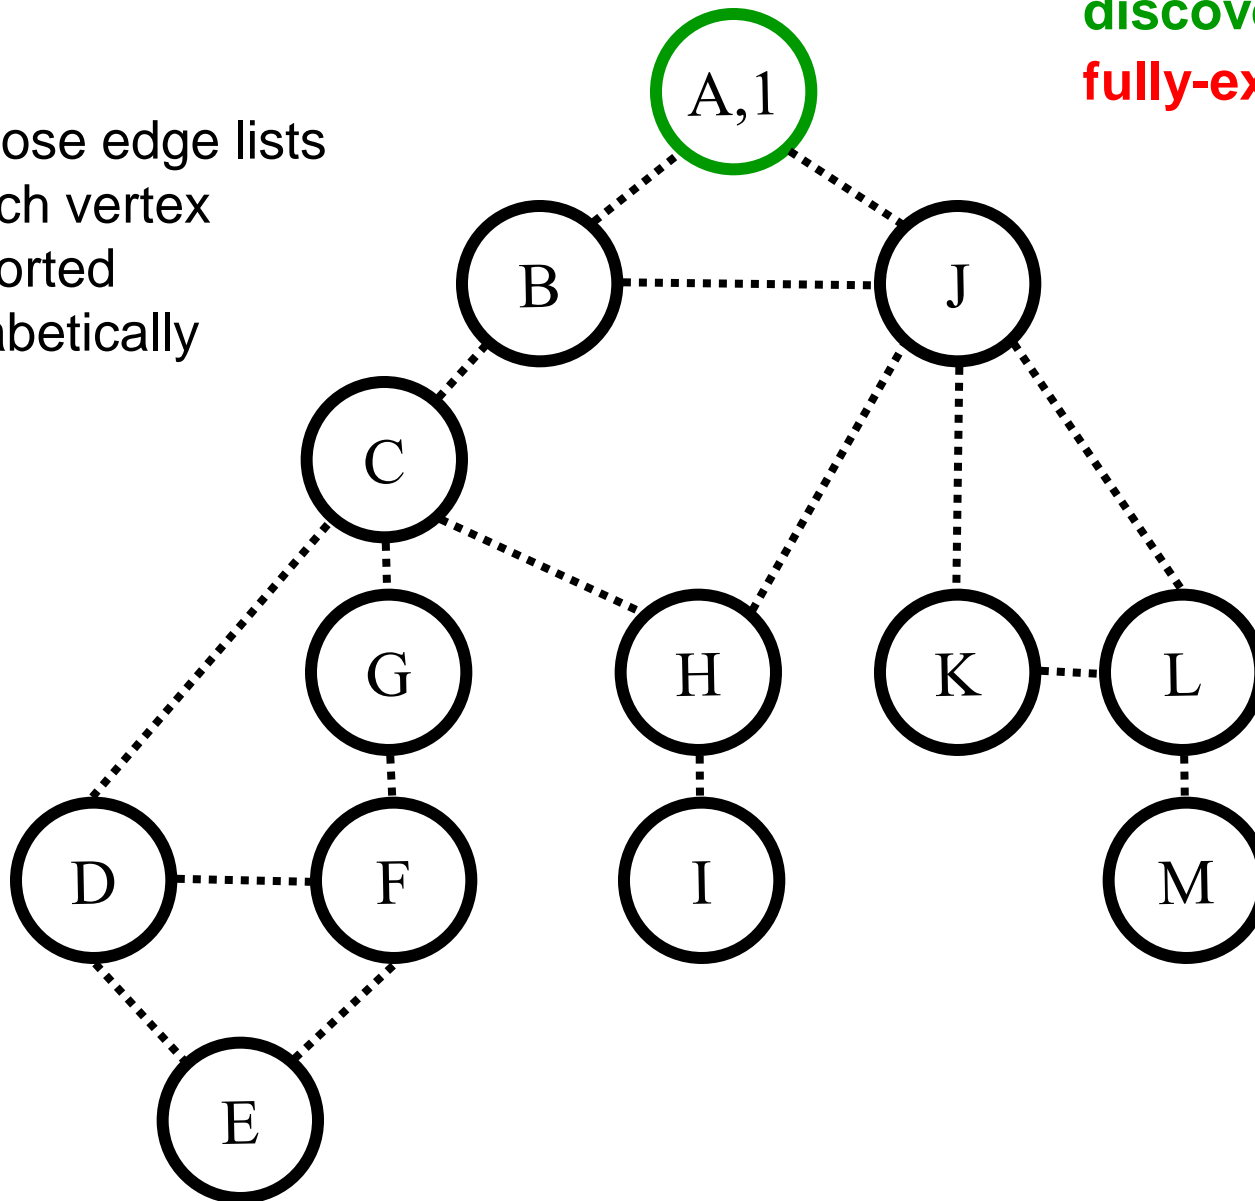

Color code:

undiscovered

discovered

fully-explored

Suppose edge lists
at each vertex
are sorted
alphabetically

Call Stack
(Edge list):

DFS(A)

Edge code:

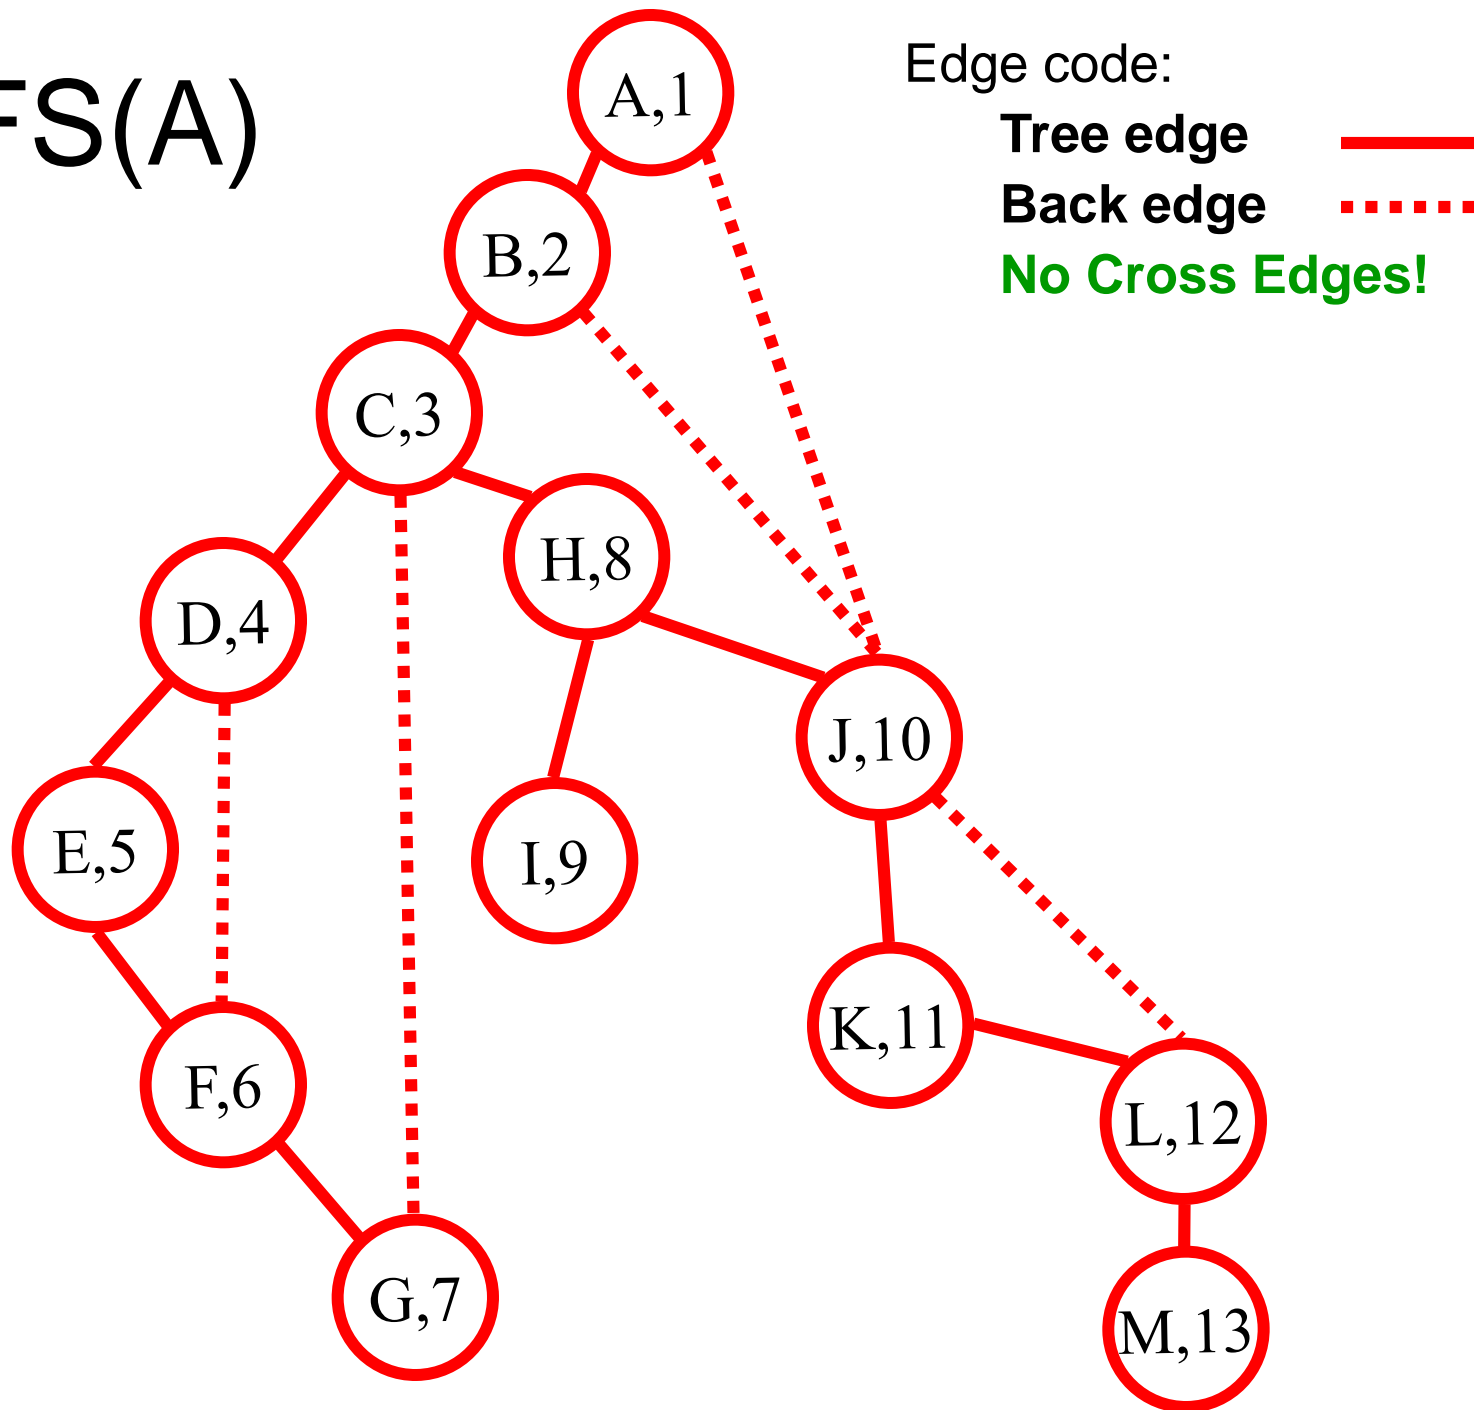

Tree edge

Back edge

DFS(A)

Properties of (undirected) DFS

Like BFS(s):

- DFS(s) visits x iff there is a path in G from s to x
So, we can use DFS to find connected components
- Edges into then-undiscovered vertices define a *tree* – the "depth first spanning tree" of G

Unlike the BFS tree:

- The DF spanning tree isn't minimum depth
- Its levels don't reflect min distance from the root
- Non-tree edges never join vertices on the same or adjacent levels

Non-Tree Edges in DFS

Lemma: For every edge $\{x, y\}$, if $\{x, y\}$ is not in DFS tree, then one of x or y is an ancestor of the other in the tree.

Proof:

Suppose that x is visited first.

Therefore $\text{DFS}(x)$ was called before $\text{DFS}(y)$

Since $\{x, y\}$ is not in DFS tree, y was visited when the edge $\{x, y\}$ was examined during $\text{DFS}(x)$

Therefore y was visited during the call to $\text{DFS}(x)$ so y is a descendant of x .

DAGs and Topological Ordering

Precedence Constraints

In a directed graph, an edge (i, j) means task i must occur before task j .

Applications

- Course prerequisite:
course i must be taken before j
- Compilation:
must compile module i before j
- Computing overflow:
output of job i is part of input to job j
- Manufacturing or assembly:
sand it before paint it

Directed Acyclic Graphs (DAG)

Def: A **DAG** is a directed acyclic graph, i.e., one that contains no directed cycles.

Def: A **topological order** of a directed graph $G = (V, E)$ is an ordering of its nodes as v_1, v_2, \dots, v_n so that for every edge (v_i, v_j) we have $i < j$.

a DAG

*a topological ordering of that DAG—
all edges left-to-right*

DAGs: A Sufficient Condition

Lemma: If G has a topological order, then G is a DAG.

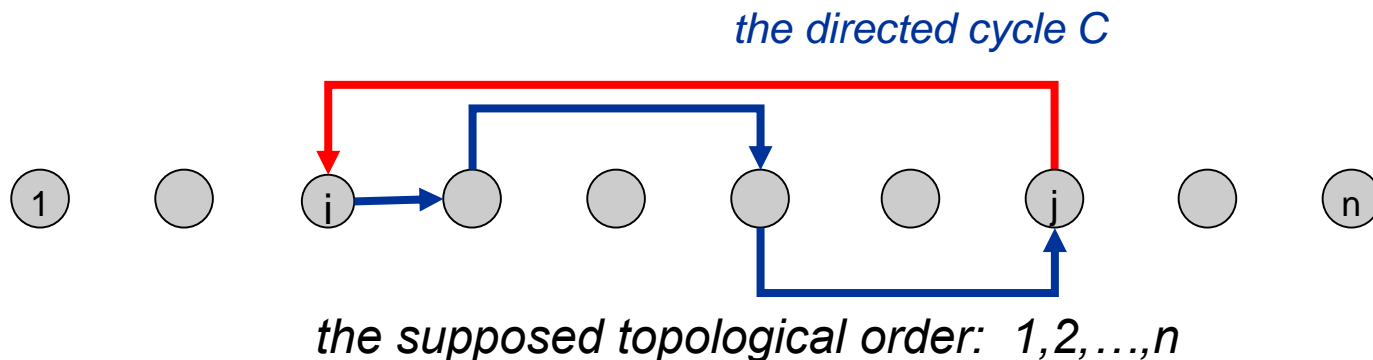

Proof. (by contradiction)

Suppose that G has a topological order $1, 2, \dots, n$ and that G also has a directed cycle C .

Let i be the lowest-indexed node in C , and let j be the node just before i ; thus (j, i) is an (directed) edge.

By our choice of i , we have $i < j$.

On the other hand, since (j, i) is an edge and $1, \dots, n$ is a topological order, we must have $j < i$, a contradiction

DAGs: A Sufficient Condition

Every DAG has a source node

Lemma: If G is a DAG, then G has a node with no incoming edges (i.e., a source).

The proof is similar to “tree has $n - 1$ edges”.

Proof. (by contradiction)

Suppose that G is a DAG and it has no source

Pick any node v , and begin following edges **backward** from v . Since v has at least one incoming edge (u, v) we can walk backward to u .

Then, since u has at least one incoming edge (x, u) , we can walk backward to x .

Repeat until we visit a node, say w , twice.

Let C be the sequence of nodes encountered between successive visits to w . C is a cycle.

DAG \Rightarrow Topological Order

Lemma: If G is a DAG, then G has a topological order

Proof. (by induction on n)

Base case: true if $n = 1$.

Hypothesis: Every DAG with $n - 1$ vertices has a topological ordering.

Inductive Step: Given DAG with $n > 1$ nodes, find a source node v .

$G - \{v\}$ is a DAG, since deleting v cannot create cycles.

Reminder: Always remove vertices/edges to use IH

By hypothesis, $G - \{v\}$ has a topological ordering.

Place v first in topological ordering; then append nodes of $G - \{v\}$ in topological order. This is valid since v has no incoming edges.

A Characterization of DAGs

Topological Order Algorithm 1: Example

Topological Order Algorithm 1: Example
