Shortest paths in directed graphs vs undirected graphs

What about the minimum spanning tree of a directed graph?

- Must specify the root r
- Branching: Out tree with root r

Assume all vertices reachable from r

Also called an arborescence

Finding a minimum branching

Finding a minimum branching

- Remove all edges going into r
- Normalize the edge weights, so the minimum weight edge coming into each vertex has weight zero

This does not change the edges of the minimum branching

Finding a minimum branching

- Consider the graph that consists of the minimum cost edge coming in to each vertex
 - If this graph is a branching, then it is the minimum cost branching
 - Otherwise, the graph contains one or more cycles
 - Collapse the cycles in the original graph to super vertices
 - Reweight the graph and repeat the process

Finding a minimum branching

Correctness Proof

Lemma 4.38 Let C be a cycle in G consisting of edges of cost 0 with r not in C . There is an optimal branching rooted at r that has exactly one edge entering C .

- The lemma justifies using the edges of the cycle in the branching
- An induction argument is used to cover the multiple levels of compressing cycles

Divide and Conquer

- Recurrences, Sections 5.1 and 5.2
- Algorithms
 - Fast Matrix Multiplication
 - Counting Inversions (5.3)
 - Closest Pair (5.4)
 - Multiplication (5.5)

Divide and Conquer

```
Array Mergesort(Array a){  
    n = a.Length;  
    if (n <= 1)  
        return a;  
  
    b = Mergesort(a[0 .. n/2]);  
    c = Mergesort(a[n/2+1 .. n-1]);  
    return Merge(b, c);  
}
```

Algorithm Analysis

- Cost of Merge
- Cost of Mergesort

$$T(n) = 2T(n/2) + cn; T(1) = c;$$

Recurrence Analysis

- Solution methods
 - Unrolling recurrence
 - Guess and verify
 - Plugging in to a “Master Theorem”

Unrolling the recurrence

Substitution

Prove $T(n) \leq cn (\log_2 n + 1)$ for $n \geq 1$

Induction:

Base Case:

Induction Hypothesis:

A better mergesort (?)

- Divide into 3 subarrays and recursively sort
- Apply 3-way merge

What is the recurrence?

Unroll recurrence for

$$T(n) = 3T(n/3) + dn$$

$$T(n) = aT(n/b) + f(n)$$

$$T(n) = T(n/2) + cn$$

Where does this recurrence arise?

Solving the recurrence exactly

$$T(n) = 4T(n/2) + n$$

$$T(n) = 2T(n/2) + n^2$$

$$T(n) = 2T(n/2) + n^{1/2}$$

Recurrences

- Three basic behaviors
 - Dominated by initial case
 - Dominated by base case
 - All cases equal – we care about the depth
