CSE 421 Section 4

Divide and Conquer
Announcements & Reminders

- HW2
  - If you think something was graded incorrectly, submit a regrade request!

- HW3
  - Was due yesterday, 10/18
  - Remember, this quarter we have a LATE PROBLEM DAYS policy, instead of a late assignments policy
    - Total of up to 10 late problem days
    - At most 2 late days per problem

- HW4
  - Due Wednesday 10/25 @ 11:59pm
Writing a Divide and Conquer Algorithm
Divide and Conquer

1. Divide instance into subparts
2. Solve the parts recursively
3. Conquer by combining the answers

The keys to this strategy:
- Come up with a baseline!
- Once you have your algo, write a recurrence for the runtime
  - Your d&c runtime should be BETTER than the baseline runtime
The Strategy (hint: it’s the same as last week!)

1. Read and Understand the Problem
2. Generate Examples
3. Produce a Baseline
4. Brainstorm and Analyze Possible Algorithms
5. Write an Algorithm
6. Show Your Algorithm is Correct
7. Optimize and Analyze the Run Time
Problem 1 – Maximum Subarray Sum

**Input:** An array of integers (possibly both positive and negative)

A single element counts as a subarray (the sum is the value of that element). No elements counts as a subarray (the sum is 0).
1. Read and Understand the Problem
Reminder of the Questions to Ask:

- What is the **input type**? (Array? Graph? Integer? Something else?)

- What is your **return type**? (Integer? List?)

- Are there any **technical terms** in the problem you should pay attention to?
Key Idea with Divide and Conquer (and other recursive algorithms)

- If you identify that you want to use a recursive algorithm paradigm like Divide and Conquer, it’s not enough to just answer those key questions on the previous slide.

- Since you know you will have recursive calls, you need to be explicit about what those recursive calls are giving you that, when combined together, gives you the solution you’re looking for.

- You should be able to state a clear English definition of the return value you want to get from the recursive calls, keeping in mind the return type, the optimality, and the range & other parameters.
Problem 1.1 – Maximum Subarray Sum

What is a clear English definition of the return value from the recursive calls?

Work through this problem with the people around you, and then we’ll go over it together!
2. Generate Examples
Good examples help with understanding now and testing later!

- You should generate two or three sample instances and the correct associated outputs.

- It’s a good idea to have some “abnormal” examples – consecutive negative numbers, very large negative numbers, only positive numbers, etc.

- *Note: In general,* you should not think of these examples as debugging examples – null or the empty list is not a good example for this step. You can worry about edge cases at the end, once you have the main algorithm idea. You should be focused on the “typical” (not edge) case.
Problem 1.2 – Maximum Subarray Sum

Generate two examples with their associated outputs. Put some effort into these! The more different from each other they are, the more likely you are to catch mistakes later.

Work through generating some examples, and then we’ll go over it together!
3. Come Up with a Baseline
Inefficient (non Divide and Conquer) First Attempt

- Review: In a time-constrained setting (like a technical interview or an exam) you often want a “baseline” algorithm. This should be an algorithm that you can implement and will give you the right answer, even if it might be slow.

- When you’re pretty sure you want to use a Divide and Conquer algorithm, this step is extremely important! You need a (brute force) non Divide and Conquer baseline (with a quick runtime analysis) so you can see whether all the recursive steps of your Divide and Conquer algo are actually saving you any time!
Problem 1.3 – Maximum Subarray Sum

What is the first algorithm that comes to mind for the problem? What would it’s running-time be? (Don’t try to do divide and conquer yet).
4. Brainstorm and Analyze Possible Algorithms
Think about How to Divide and Conquer

- Questions to help you brainstorm out your Divide and Conquer algo:
  - How do you want to split up the problem?
  - What is returned from the recursive calls? (hint: look back at part 1)
  - Imagine you have the answers from those recursive calls; what is there still to handle?

- When you have time, it's a good idea to try to run through your idea with some of the examples you came up with earlier, and see whether you get the correct output (especially as you try to transition from your brainstorming to formalizing your algorithm)
Problem 1.4 – Maximum Subarray Sum

For each call SubarraySumDC(A[1..n]) answer these questions:
How do you want to split up the problem?

What is returned from the recursive calls?

Imagine you have the answers from those recursive calls; what is there still to handle?
5. Write an Algorithm
Translate the brainstorm into an algorithm!

- We need to take those ideas we were just noodling on and write them into an algorithm!
- We can start with formalizing our ideas from earlier, but then we still need to figure out how to deal with those subarrays that cross from one half to the other…
6. Show Your Algorithm is Correct
Problem 1.6 – Maximum Subarray Sum

Write a proof of correctness.

Hint: recursion ≈ induction

IH is always strong induction style “my program is correct for all inputs of size ≤ $k$”

Work on this proof with the people around you, and then we’ll go over it together!
7. Optimize and Analyze the Run Time
Problem 1.7 – Maximum Subarray Sum

Write the big-O of your code and justify the running time with a few sentences.
That's All, Folks!

Thanks for coming to section this week! Any questions?
