DNA Replication

DNA Replication: Basics

Issues & Complications, I

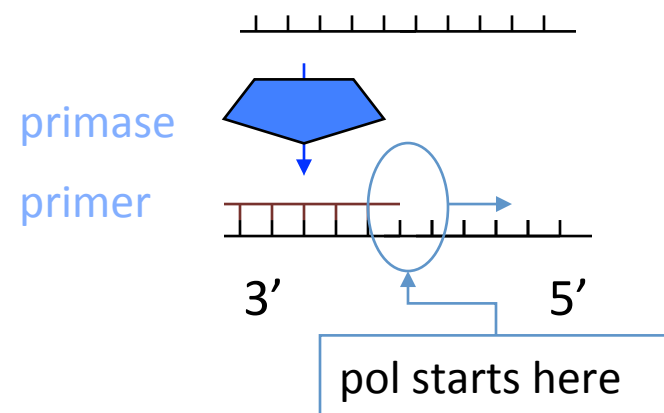

1st ~10 nt's added are called the *primer*

In simple model, DNA pol has 2 jobs: prime & extend

Priming is error-prone

So, specialized *primase* does the priming; pol specialized for fast, accurate extension

Still doesn't solve the accuracy problem (hint: primase makes an *RNA* primer)

Issue 2: Rep Forks & Helices

“Replication Fork”: DNA double helix is progressively unwound by a DNA **helicase**, and both resulting single strands are duplicated

DNA **polymerase** synthesizes new strand 5' → 3' (reading its template strand 3' → 5')

That means on one (the “leading”) strand, DNA pol is chasing/pushing the replication fork

But on the other “lagging” strand, DNA pol is running away from it.

Issue 3: Fragments

Lagging strand gets a series of “Okazaki fragments” of DNA (~200nt in eukaryotes) following each primer

The RNA primers are later removed by a *nuclease* and *DNA pol* fills gaps (more accurate than primase; primed by *DNA* from adjacent Okazaki frag

Fragments joined by *ligase*

Issue 4: Coord of Leading/Lagging

(Replication starts at about 1:40)

Issue 5: Twirls & Tangles

Unwinding helix (~10 nucleotides per turn) would cause stress.

Topoisomerase I cuts DNA backbone on *one* strand, allowing it to spin about the remaining bond, relieving stress

Topoisomerase II can cut & rejoin *both* strands, after allowing another double strand to pass through the gap, de-tangling it.

Issue 6: Proofreading

Error rate of pol itself is $\sim 10^{-4}$, but overall rate is 10^{-9} , due to proofreading & repair, e.g.

- pol itself can back up & cut off a mismatched base if one happens to be inserted

- priming the new strand is hard to do accurately, hence RNA primers, later removed & replaced

- other enzymes scan helix for “bulges” caused by base mismatch, figure out which strand is original, cut away new (faulty) copy; DNA pol fills gap

- which strand is original? Bacteria: “methylate” some A’s, eventually. Euks: strand nicking

Replication Summary

Speed: 50 (eukaryotes) to
500 (prokaryotes) bp/sec

Accuracy: 1 error per 10^9 bp

Complex & highly optimized

Highly similar across all living cells
