CSE 444: Database Internals

Lectures 15

Optimistic Concurrency Control

Pessimistic v.s. Optimistic

- Pessimistic CC (locking)
  - Prevents unserializable schedules
  - Never abort for serializability (but may abort for deadlocks)
  - Best for workloads with high level of contention
- Optimistic CC (timestamp, validation, SI)
  - Assume schedule will be serializable
  - Abort when conflicts detected
  - Best for workloads with low level of contention

Outline

- Concurrency control by timestamps (18.8)
- Concurrency control by validation (18.9)
- Snapshot Isolation

Timestamps

- Each transaction receives unique timestamp TS(T)

Could be:

- The system's clock
- A unique counter, incremented by the scheduler

Timestamps

Main invariant:

The timestamp order defines
the serialization order of the transaction

Will generate a schedule that is view-equivalent to a serial schedule, and recoverable

Timestamps

With each element X, associate

- RT(X) = the highest timestamp of any transaction U that read X
- WT(X) = the highest timestamp of any transaction U that wrote X
- C(X) = the commit bit: true when transaction with highest timestamp that wrote X committed

Main Idea

For any $r_T(X)$ or $w_T(X)$ request, check for conflicts:

- $w_U(X)$ . . . $r_T(X)$
- $r_U(X)$ . . . $w_T(X)$
- $w_U(X)$ . . . $w_T(X)$

How do we check if Read too late ?

Write too late ?

Main Idea

For any $r_T(X)$ or $w_T(X)$ request, check for conflicts:

- $w_U(X) \ldots r_T(X)$
- $r_U(X) \ldots w_T(X)$
- $w_U(X) \ldots w_T(X)$

How do we check if Read too late ?

Write too late ?

When T requests $r_T(X)$, need to check $TS(U) \leq TS(T)$

Read Too Late

- T wants to read X

START(T) … START(U) … $w_U(X)$ . . . $r_T(X)$

Read Too Late

- T wants to read X

START(T) … START(U) … $w_U(X)$ . . . $r_T(X)$

If WT(X) > TS(T) then need to rollback T !

Write Too Late

- T wants to write X

START(T) … START(U) … $r_U(X)$ . . . $w_T(X)$

Write Too Late

- T wants to write X

START(T) … START(U) … $r_U(X)$ . . . $w_T(X)$

If RT(X) > TS(T) then need to rollback T !

Thomas' Rule

But we can still handle it:

- T wants to write X

START(T) … START(V) … $w_V(X)$ . . . $w_T(X)$

If $RT(X) \leq TS(T)$ and $WT(X) > TS(T)$
then don't write X at all !

Why does this work?

Thomas' Rule

But we can still handle it:

- T wants to write X

START(T) … START(V) … $w_V(X)$ . . . $w_T(X)$

If $RT(X) \leq TS(T)$ and $WT(X) > TS(T)$
then don't write X at all !

Why does this work?

View-serializable schedule

View-Serializability

- By using Thomas' rule we do obtain a view-serializable schedule

Summary So Far

Only for transactions that do not abort
Otherwise, may result in non-recoverable schedule

Transaction wants to read element X

If WT(X) > TS(T) then ROLLBACK
Else READ and update RT(X) to larger of TS(T) or RT(X)

Transaction wants to write element X

If RT(X) > TS(T) then ROLLBACK
Else if WT(X) > TS(T) ignore write & continue (Thomas Write Rule)
Otherwise, WRITE and update WT(X) =TS(T)

Ensuring Recoverable Schedules

Recall:

- Schedule avoids cascading aborts if whenever a transaction reads an element, then the transaction that wrote it must have already committed

- Use the commit bit C(X) to keep track if the transaction that last wrote X has committed

Ensuring Recoverable Schedules

Read dirty data:

- T wants to read X, and WT(X) < TS(T)
- Seems OK, but…

START(U) … START(T) … $w_U(X)$. . . $r_T(X)$… ABORT(U)

If C(X)=false, T needs to wait for it to become true

Ensuring Recoverable Schedules

Thomas' rule needs to be revised:

- T wants to write X, and WT(X) > TS(T)
- Seems OK not to write at all, but …

START(T) … START(U)… w_U(X). . . w_T(X)… ABORT(U)

If C(X)=false, T needs to wait for it to become true

Timestamp-based Scheduling

- When a transaction T requests $r_T(X)$ or $w_T(X)$, the scheduler examines RT(X), WT(X), C(X), and decides one of:

- To grant the request, or
- To rollback T (and restart with later timestamp)
- To delay T until C(X) = true

Timestamp-based Scheduling

RULES including commit bit

- There are 4 long rules in Sec. 18.8.4
- You should be able to derive them yourself, based on the previous slides
- Make sure you understand them !

READING ASSIGNMENT: 18.8.4

Timestamp-based Scheduling (Read 18.8.4 instead!)

Transaction wants to READ element X
- If WT(X) > TS(T) then ROLLBACK
- Else If C(X) = false, then WAIT
- Else READ and update RT(X) to larger of TS(T) or RT(X)

Transaction wants to WRITE element X
- If RT(X) > TS(T) then ROLLBACK
- Else if WT(X) > TS(T)
  - Then If C(X) = false then WAIT
    - else IGNORE write (Thomas Write Rule)
- Otherwise, WRITE, and update WT(X)=TS(T), C(X)=false

Summary of Timestamp-based Scheduling

- View-serializable
- Avoids cascading aborts (hence: recoverable)
- Does NOT handle phantoms
  - These need to be handled separately, e.g. predicate locks

Multiversion Timestamp

- When transaction T requests r(X) but WT(X) > TS(T), then T must rollback
- Idea: keep multiple versions of X: $X_t, X_{t-1}, X_{t-2}, \ldots$

$$TS(X_t) > TS(X_{t-1}) > TS(X_{t-2}) > \ldots$$

Details

- When $w_T(X)$ occurs,
  create a new version, denoted X_t where t = TS(T)

- When $r_T(X)$ occurs,
  find most recent version X_t such that t < TS(T)
  Notes:
  - $WT(X_t)$ = t and it never changes
  - $RT(X_t)$ must still be maintained to check legality of writes

- Can delete X_t if we have a later version X_{t1} and all active transactions T have TS(T) > t1

Example (in class)

X_3 X_9 X_{12} X_{18}

$R_6(X)$ -- what happens?

$W_{14}(X)$ – what happens?

$R_{15}(X)$ – what happens?

$W_5(X)$ – what happens?

When can we delete X_3?

Example w/ Basic Timestamps

T_1	T_2	T_3	T_4	A
150	200	175	225	RT=0 WT=0
$R_1(A)$				RT=150
$W_1(A)$				WT=150
	$R_2(A)$			RT=200
	$W_2(A)$			WT=200
		$R_3(A)$		
		Abort		
			$R_4(A)$	RT=225

Example w/ Multiversion

T_1	T_2	T_3	T_4	A_0	A_{150}	A_{200}
150	200	175	225			
$R_1(A)$				RT=150		
$W_1(A)$					Create	
	$R_2(A)$				RT=200	
	$W_2(A)$					Create
		$R_3(A)$			RT=200	
		$W_3(A)$				
		abort				
			$R_4(A)$			RT=225

Outline

- Concurrency control by timestamps (18.8)
- Concurrency control by validation (18.9)
- Snapshot Isolation

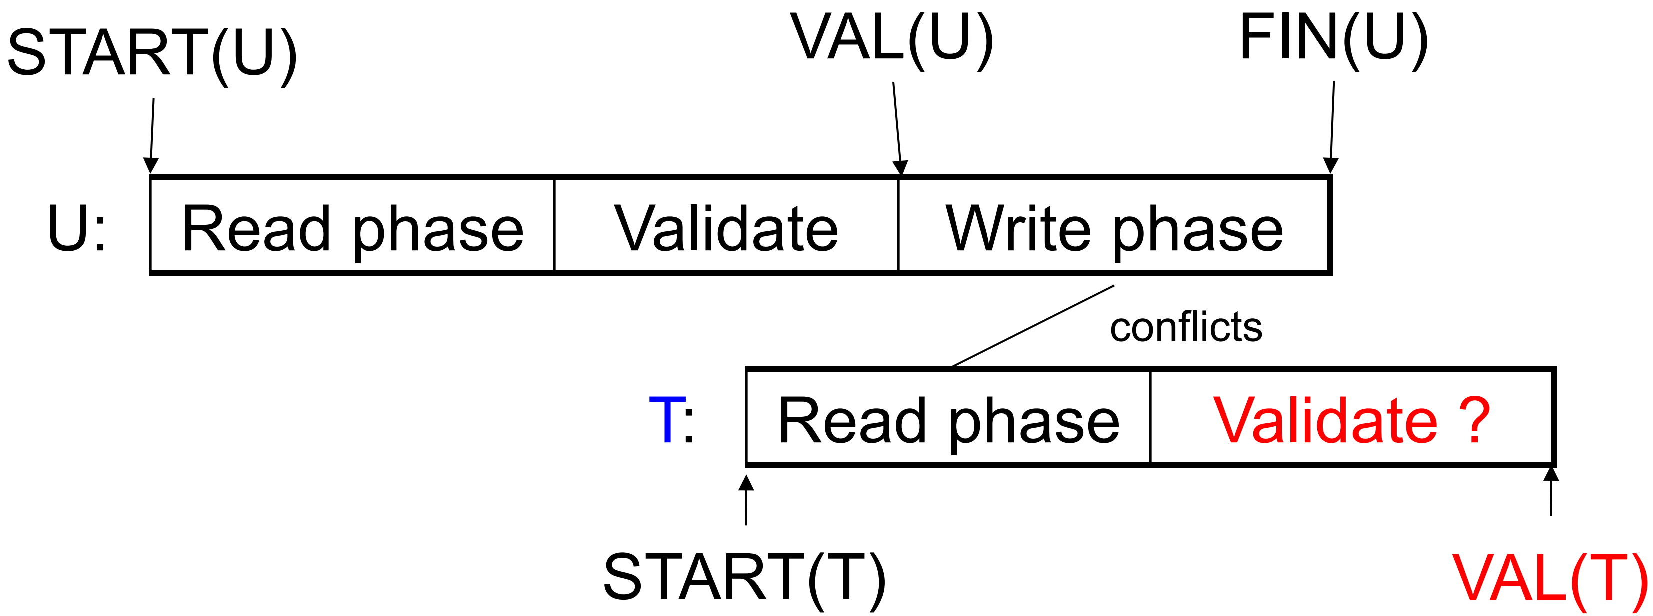
Concurrency Control by Validation

- Each transaction T defines:
  - Read set RS(T) = the elements it reads
  - Write set WS(T) = the elements it writes

- Each transaction T has three phases:
  - Read phase; time = START(T)
  - Validate phase (may need to rollback); time = VAL(T)
  - Write phase; time = FIN(T)

Main invariant: the serialization order is VAL(T)

Avoid $r_T(X)$ - $w_U(X)$ Conflicts

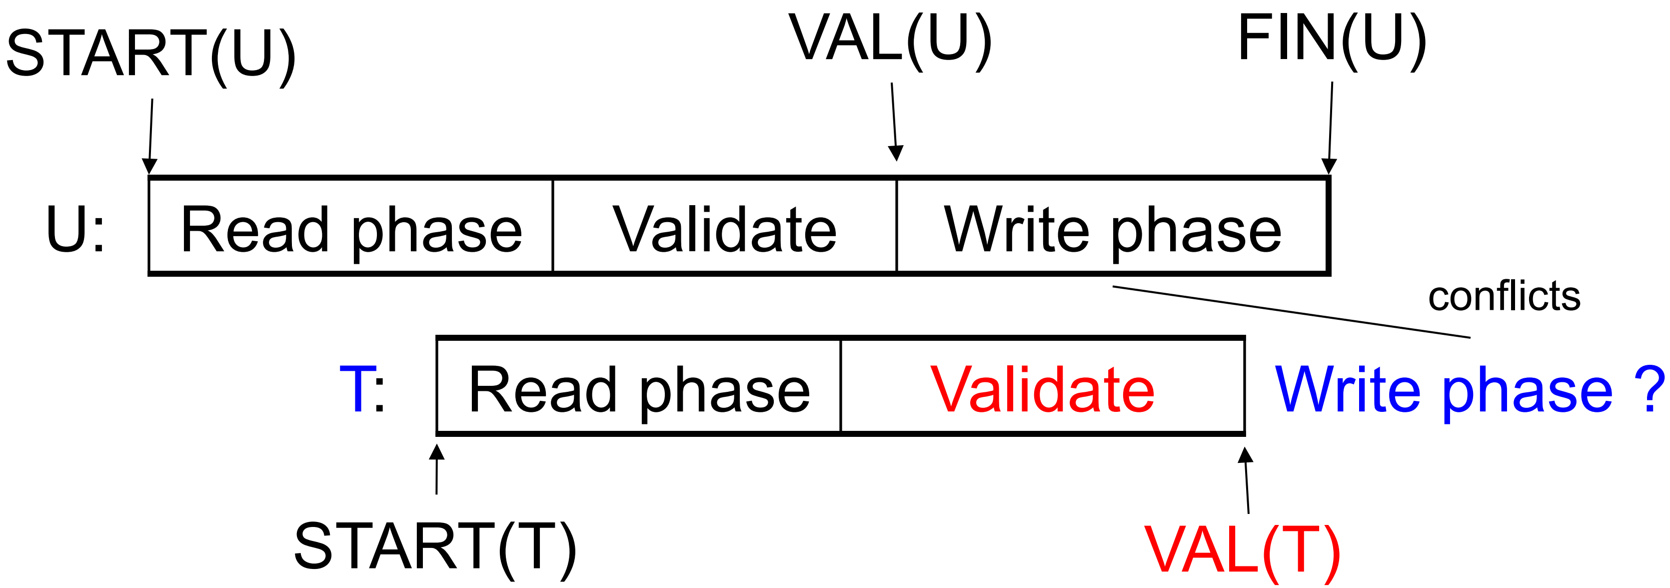


IF RS(T) ∩ WS(U) and FIN(U) > START(T)

(U has validated and U has not finished before T begun)

Then ROLLBACK(T)

Avoid $w_T(X)$ - $w_U(X)$ Conflicts



IF WS(T) ∩ WS(U) and FIN(U) > VAL(T)

(U has validated and U has not finished before T validates)

Then ROLLBACK(T)

Outline

- Concurrency control by timestamps (18.8)
- Concurrency control by validation (18.9)
- Snapshot Isolation
  – Not in the book, but good overview in Wikipedia
  – Better: pay attention in class!

SI Overview

- Each transactions receives a timestamp TS(T)
- Transaction T sees snapshot at time TS(T) of the database
- Write/write conflicts resolved by “first committer wins” rule
  - Loser gets aborted
- Read/write conflicts are ignored
- When T commits, its dirty pages are written to disk

SI Details

- Multiversion concurrency control:
  - Versions of X: X_{t1}, X_{t2}, X_{t3}, . . .
- When T reads X, return $X_{TS(T)}$.
- When T writes X (to avoid lost update):
  - If latest version of X is TS(T) then proceed
  - If C(X) = true then abort
  - If C(X) = false then wait
- When T commits, write its updates to disk

What Works and What Not

- No dirty reads (Why ?)
- No inconsistent reads (Why ?)
- No lost updates (“first committer wins”)

- Moreover: no reads are ever delayed

- However: read-write conflicts not caught !

Write Skew

```
T1:
   READ(X);
   if X >= 50
         then Y = -50; WRITE(Y)
   COMMIT
```

```
T2:
   READ(Y);
   if Y >= 50
         then X = -50; WRITE(X)
   COMMIT
```

In our notation:

$R_1(X), R_2(Y), W_1(Y), W_2(X), C_1, C_2$

Starting with X=50,Y=50, we end with X=-50, Y=-50.
Non-serializable !!!

Write Skews Can Be Serious

- Acidicland had two viceroys, Delta and Rho
- Budget had two registers: taXes, and spendYng
- They had high taxes and low spending…

Delta:	Rho:
READ(taXes); if taXes = 'High' then { spendYng = 'Raise'; WRITE(spendYng) } COMMIT	READ(spendYng); if spendYng = 'Low' then {taXes = 'Cut'; WRITE(taXes) } COMMIT

… and they ran a deficit ever since.

Discussion: Tradeoffs

- Optimistic CC: Locks
  - Great when there are many conflicts
  - Poor when there are few conflicts
- Pessimistic CC: Timestamps, Validation, SI
  - Poor when there are many conflicts (rollbacks)
  - Great when there are few conflicts
- Compromise
  - READ ONLY transactions → timestamps
  - READ/WRITE transactions → locks

Commercial Systems

Always check documentation!

- DB2: Strict 2PL
- SQL Server:
  - Strict 2PL for standard 4 levels of isolation
  - Multiversion concurrency control for snapshot isolation
- PostgreSQL: SI; recently: seralizable SI (!)
- Oracle: SI
