

CSE 444: Database Internals

Lecture 12

Query Optimization (part 3)

Acknowledgments

Today's lecture focuses on how to actually implement the Selinger optimizer

Designed to help you with Lab 4

Many slides from Sam Madden at MIT

Selinger Optimizer

Problem:

- How to order a series joins over N tables A,B,C,...
E.g. A.a = B.b AND A.c = D.d AND B.e = C.f
- N! ways to order joins; e.g. ABCD, ACBD,
- $C_{N-1} = \frac{1}{N} \binom{2(N-1)}{N-1}$ plans/ordering; e.g. (((AB)C)D), ((AB)(CD)))
- Multiple implementations (hash, nested loops)
- Naïve approach does not scale
 - E.g. N = 20, #join orders 20! = 2.4 x 10¹⁸; many more plans

Selinger Optimizer

- Only **left-deep plan**: $((AB)C)D$ – eliminate C_{N-1} .
- Push down selections
- Don't consider cartesian products
- Dynamic programming algorithm

Dynamic Programming

OrderJoins:

SimpleDB Lab4:
you implement **orderJoins**

R = set of relations to join

For d = 1 to N: /* where N = |R| */

For S in {all size-d subsets of R}:

Use: **enumerateSubsets**

optjoin(S) = (S - a) join a,

where a is the single relation that minimizes:

cost(**optjoin**(S - a)) +
min.cost to join (S - a) with a +
min.access cost for a

Use:
computerCostAndCardOfSubplan

Note: **optjoin**(S-a) is cached from previous iterations

Example

- **orderJoins(A, B, C, D)**
- Assume all joins are NL

Subplan S	optJoin(S)	Cost(OptJoin(S))
A		

Example

- **orderJoins(A, B, C, D)**
- Assume all joins are NL

Subplan S	optJoin(S)	Cost(OptJoin(S))
A	Index scan	100
B	Seq. scan	50
C	Seq scan	120
D	B+tree scan	400

- $d = 1$
 - A = best way to access A
(sequential scan, predicate-pushdown on index, etc)
 - B = best way to access B
 - C = best way to access C
 - D = best way to access D
- Total number of steps: choose(N, 1)

Example

- **orderJoins(A, B, C, D)**
- $d = 2$
 - $\{A, B\} = AB$ or BA
use previously computed
best way to access A and B

Subplan S	optJoin(S)	Cost(OptJoin(S))
A	Index scan	100
B	Seq. scan	50
...		

Example

- **orderJoins(A, B, C, D)**
- $d = 2$
 - {A,B} = AB or BA
use previously computed
best way to access A and B

Subplan S	optJoin(S)	Cost(OptJoin(S))
A	Index scan	100
B	Seq. scan	50
...		
{A, B}	BA	156

Example

- **orderJoins(A, B, C, D)**

- $d = 2$

- $\{A, B\} = AB$ or BA
use previously computed
best way to access A and B
- $\{B, C\} = BC$ or CB

Subplan S	optJoin(S)	Cost(OptJoin(S))
A	Index scan	100
B	Seq. scan	50
...		
{A, B}	BA	156
{B, C}	BC	98

Example

- **orderJoins(A, B, C, D)**

- $d = 2$

- $\{A, B\} = AB$ or BA
use previously computed
best way to access A and B
- $\{B, C\} = BC$ or CB

Subplan S	optJoin(S)	Cost(OptJoin(S))
A	Index scan	100
B	Seq. scan	50
...		
$\{A, B\}$	BA	156
$\{B, C\}$	BC	98

Example

- **orderJoins(A, B, C, D)**

- $d = 2$

- {A,B} = AB or BA
use previously computed
best way to access A and B

- {B,C} = BC or CB
- {C,D} = CD or DC
- {A,C} = AC or CA
- {B,D} = BD or DB
- {A,D} = AD or DA

Subplan S	optJoin(S)	Cost(OptJoin(S))
A	Index scan	100
B	Seq. scan	50
...		
{A, B}	BA	156
{B, C}	BC	98
.....		

Example

- **orderJoins(A, B, C, D)**

- $d = 2$

- $\{A, B\} = AB$ or BA
use previously computed
best way to access A and B

- $\{B, C\} = BC$ or CB
- $\{C, D\} = CD$ or DC
- $\{A, C\} = AC$ or CA
- $\{B, D\} = BD$ or DB
- $\{A, D\} = AD$ or DA

- Total number of steps: $\text{choose}(N, 2) \times 2$

Subplan S	optJoin(S)	Cost(OptJoin(S))
A	Index scan	100
B	Seq. scan	50
...		
$\{A, B\}$	BA	156
$\{B, C\}$	BC	98
.....		

Example

- **orderJoins(A, B, C, D)**

- $d = 3$

- $\{A, B, C\} =$

Remove A: compare $A(\{B, C\})$ to $(\{B, C\})A$

Subplan S	optJoin(S)	Cost(OptJoin(S))
A	Index scan	100
B	Seq. scan	50
....		
{A, B}	BA	156
{B, C}	BC	98
....		

Example

- **orderJoins(A, B, C, D)**

- $d = 3$

– $\{A, B, C\} =$

Remove A: compare $A(\boxed{B, C})$ to $(\{B, C\})A$

Subplan S	optJoin(S)	Cost(OptJoin(S))
A	Index scan	100
B	Seq. scan	50
....		
{A, B}	BA	156
{B, C}	BC	98
....		

optJoin(B,C)
and its cost are
already cached
in table

Example

- **orderJoins(A, B, C, D)**

- $d = 3$

– $\{A, B, C\} =$

Remove A: compare A(**$\{B, C\}$**) to $(\{B, C\})A$

Remove B: compare B($\{A, C\}$) to $(\{A, C\})B$

Remove C: compare C($\{A, B\}$) to $(\{A, B\})C$

Subplan S	optJoin(S)	Cost(OptJoin(S))
A	Index scan	100
B	Seq. scan	50
....		
$\{A, B\}$	BA	156
$\{B, C\}$	BC	98
....		
$\{A, B, C\}$	BAC	500
.....		

optJoin(B,C)
and its cost are
already cached
in table

Example

- **orderJoins(A, B, C, D)**

- $d = 3$

– $\{A, B, C\} =$

Remove A: compare A($\{B, C\}$) to $(\{B, C\})A$

Remove B: compare B($\{A, C\}$) to $(\{A, C\})B$

Remove C: compare C($\{A, B\}$) to $(\{A, B\})C$

Subplan S	optJoin(S)	Cost(OptJoin(S))
A	Index scan	100
B	Seq. scan	50
....		
{A, B}	BA	156
{B, C}	BC	98
...		
{A, B, C}	BAC	500
.....		

optJoin(B,C)
and its cost are
already cached
in table

Example

Subplan S	optJoin(S)	Cost(OptJoin(S))
A	Index scan	100
B	Seq. scan	50
....		
{A, B}	BA	156
{B, C}	BC	98
...		
{A, B, C}	BAC	500
.....		

- **orderJoins(A, B, C, D)**

- $d = 3$

– {A,B,C} =

Remove A: compare A({B,C}) to ({B,C})A

Remove B: compare B({A,C}) to ({A,C})B

Remove C: compare C({A,B}) to ({A,B})C

– {A,B,D} =

Remove A: compare A({B,D}) to ({B,D})A

...

– {A,C,D} = ...

– {B,C,D} = ...

- Total number of steps: $\text{choose}(N, 3) \times 3 \times 2$

optJoin(B,C)
and its cost are
already cached
in table

Example

- **orderJoins(A, B, C, D)**

- $d = 4$
 - $\{A, B, C, D\} =$

Subplan S	optJoin(S)	Cost(OptJoin(S))
A	Index scan	100
B	Seq. scan	50
{A, B}	BA	156
{B, C}	BC	98
{A, B, C}	BAC	500
{B, C, D}	DBC	150
.....		

Remove A: compare A(**{B, C, D}**) to ({B, C, D})A
 Remove B: compare B({A, C, D}) to ({A, C, D})B
 Remove C: compare C({A, B, D}) to ({A, B, D})C
 Remove D: compare D({A, B, C}) to ({A, B, C})D

optJoin(B, C, D)
and its cost are
already cached
in table

- Total number of steps: $\text{choose}(N, 4) \times 4 \times 2$

Complexity

- Total #subsets considered
 - $\text{Choose}(N, 1) + \text{Choose}(N, 2) + \dots + \text{Choose}(N, N)$
 - All nonempty subsets of a size N set: $2^N - 1$
 - Equivalently: number of binary strings of size N , except $00\dots 0$:
~~000~~, 001, 010, 011, 100, 101, 110, 111

Complexity

- Total #subsets considered
 - $\text{Choose}(N, 1) + \text{Choose}(N, 2) + \dots + \text{Choose}(N, N)$
 - All nonempty subsets of a size N set: $2^N - 1$
 - Equivalently: number of binary strings of size N , except $00\dots 0$:
~~000~~, 001, 010, 011, 100, 101, 110, 111
- For each subset of size d :
 - d ways to remove one element
 - 2 ways for compute AB or BA (except when $d=2$, when we already accounted for that – why?)

Complexity

- Total #subsets considered
 - $\text{Choose}(N, 1) + \text{Choose}(N, 2) + \dots + \text{Choose}(N, N)$
 - All nonempty subsets of a size N set: $2^N - 1$
 - Equivalently: number of binary strings of size N , except $00\dots 0$:
~~000~~, 001, 010, 011, 100, 101, 110, 111
- For each subset of size d :
 - d ways to remove one element
 - 2 ways for compute AB or BA (except when $d=2$, when we already accounted for that – why?)
- Total #plans considered
 - $\text{Choose}(N, 1) + 2 \text{Choose}(N, 2) + \dots + N \text{Choose}(N, N)$
 - Equivalently: total number of 1's in all strings of size N
 - $N 2^{N-1}$ because every 1 occurs 2^{N-1} times
 - Need to further multiply by 2, to account for AB or BA

Interesting Orders

- Some query plans produce data in sorted order
 - E.g scan over a primary index, merge-join
 - Called *interesting order*
- Next operator may use this order
 - E.g. can be another merge-join
- For each subset of relations, compute multiple optimal plans, one for each interesting order
- Increases complexity by factor $k+1$, where k =number of interesting orders

Why Left-Deep

Asymmetric, cost depends on the order

- Left: Outer relation Right: Inner relation
- For nested-loop-join, we try to load the outer (typically smaller) relation in memory, then read the inner relation one page at a time
$$B(R) + B(R) * B(S) \text{ or } B(R) + B(R)/M * B(S)$$
- For index-join,
we assume right (inner) relation has index

Why Left-Deep

- Advantages of left-deep trees?
 1. Fits well with standard join algorithms (nested loop, one-pass), more efficient
 2. One pass join: Uses smaller memory
 1. $((R, S), T)$, can reuse the space for R while joining (R, S) with T
 2. $(R, (S, T))$: Need to hold R , compute (S, T) , then join with R , worse if more relations
 3. Nested loop join, consider top-down iterator `next()`
 1. $((R, S), T)$, Reads the chunks of (R, S) once, reads stored base relation T multiple times
 2. $(R, (S, T))$: Reads the chunks of R once, reads computed relation (S, T) multiple times, either more time or more space

Implementation in SimpleDB (lab4)

1. [JoinOptimizer.java](#) (and the classes used there)

2. Returns vector of “[LogicalJoinNode](#)”

Two base tables, two join attributes, predicate

e.g. $R(a, b), S(c, d), T(a, f), U(p, q)$

$(R, S, R.a, S.c, =)$

Recall that SimpleDB keeps all attributes of R, S after their join $R.a, R.b, S.c, S.d$

3. Output vector looks like:

[<\(R, S, R.a, S.c\), \(R, T, R.b, T.f\), \(S, U, S.d, U.q\)>](#)

Implementation in SimpleDB (lab4)

Any advantage of returning pairs?

- Flexibility to consider all linear plans
 $\langle (R, S, R.a, S.c), (R, T, R.b, T.f), (U, S, U.q, S.d) \rangle$

More Details:

- You mainly need to implement “`orderJoins(..)`”
- “`CostCard`” data structure stores a plan, its cost and cardinality: you would need to estimate them
- “`PlanCache`” stores the table in dyn. Prog:

Maps a set of LJO to
a vector of LJO (best plan for the vector),
its cost, and its cardinality

LJO = LogicalJoinNode
