CSE 444 - Winter 2018

Motivation

- Goal: Better use **distributed memory** in a cluster
- Observation:
 - Modern data analytics involves **iterations**
 - Users also want to do **interactive** data mining
 - In both cases, want to **keep intermediate data in memory and reuse it**
 - MapReduce does not support this scenario well
 - Requires writing data to disk between jobs

CSE 444 - Winter 2018

Approach

- [New abstraction: Resilient Distributed Datasets](#)
- RDD properties
 - Parallel data structure
 - Can be persisted in memory
 - Fault-tolerant
 - Users can manipulate RDDs with rich set of operators

CSE 444 - Winter 2018

RDD Details

- An RDD is a [partitioned collection of records](#)
 - RDD's are typed: RDD[Int] is an RDD of integers
- An RDD is [read only](#)
 - This means no updates to individual records
 - This is to contrast with in-memory key-value stores
- To create an RDD
 - Execute a [deterministic](#) operation on another RDD
 - Or on data in stable storage
 - Example operations: map, filter, and join

RDD Materialization

- Users control persistence and partitioning
- [Persistence](#)
 - Should we materialize this RDD in memory?
- [Partitioning](#)
 - Users can specify key for partitioning an RDD

CSE 444 - Winter 2018

Let's think about it...

- So RDD is a lot like a view in a parallel engine
- A view that can be materialized in memory
- A materialized view that can be physically tuned
 - Tuning: How to partition for maximum performance

Spark Programming Interface

- RDDs implemented in new Spark system
- Spark exposes RDDs through a **language-integrated API** similar to DryadLINQ but in Scala
- Later Spark was extended with SQL

CSE 444 - Winter 2018

Why Scala?

From Matei Zaharia (Spark lead author): "When we started Spark, we wanted it to have a concise API for users, which Scala did well. At the same time, we wanted it to be fast (to work on large datasets), so many scripting languages didn't fit the bill. Scala can be quite fast because it's statically typed and it compiles in a known way to the JVM. Finally, running on the JVM also let us call into other Java-based big data systems, such as Cassandra, HDFS and HBase.

Since we started, we've also added APIs in Java (which became much nicer with Java 8) and Python"

Querying/Processing RDDs

- Programmer first defines RDDs through **transformations** on data in stable storage
 - Map
 - Filter
 - ...
- Then, can use RDDs in **actions**
 - Action returns a value to app or exports to storage
 - Count (counts elements in dataset)
 - Collect (returns elements themselves)
 - Save (output to stable storage)

CSE 444 - Winter 2018

Example (from paper)

Search logs stored in HDFS

```
lines = spark.textFile("hdfs://...")
errors = lines.filter(_.startsWith("Error"))
errors.persist()
errors.collect()
errors.filter(_.contains("MySQL")).count()
```

CSE 444 - Winter 2018

More on Programming Interface

- Large set of **pre-defined transformations**:
 - Map, filter, flatMap, sample, groupByKey, reduceByKey, union, join, cogroup, crossProduct, ...
- Small set of **pre-defined actions**:
 - Count, collect, reduce, lookup, and save
- Programming Interface includes **iterations**

CSE 444 - Winter 2018

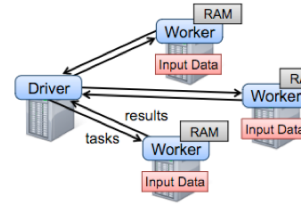

More Complex Example

```
val points = spark.textFile(...)
                      .map(parsePoint).persist()
var w = // random initial vector
for (i <- 1 to ITERATIONS) {
  val gradient = points.map{ p =>
    p.x * (1/(1+exp(-p.y*(w dot p.x)))-1)*p.y
  }.reduce((a,b) => a+b)
  w -= gradient
}
```

Spark Runtime

- 1) Input data in HDFS
Or other Hadoop
input source
- 2) User writes
driver program
- 3) System ships code
to workers

Figure 2: Spark runtime. The user's driver program launches multiple workers, which read data blocks from a distributed file system and can persist computed RDD partitions in memory.

CSE 444 - Winter 2018

Query Execution Details

- **Lazy evaluation**
 - RDDs are not evaluated until an action is called
- **In memory caching**
 - Spark workers are long-lived processes
 - RDDs can be materialized in memory in workers
 - Base data is not cached in memory

CSE 444 - Winter 2018

Key Challenge

- How to provide fault-tolerance efficiently?

CSE 444 - Winter 2018

Fault-Tolerance Through Lineage

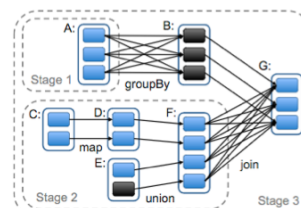

Represent RDD with 5 pieces of information

- A set of **partitions**
- A set of **dependencies** on parent partitions
 - Distinguishes between **narrow** (one-to-one)
 - And **wide** dependencies (one-to-many)
- **Function** to compute dataset based on parent
- **Metadata** about partitioning scheme and data placement

RDD = Distributed relation + lineage

CSE 444 - Winter 2018

More Details on Execution

Scheduler builds a DAG of stages based on lineage graph of desired RDD.

Pipelined execution within stages

Synchronization barrier with materialization before shuffles

If a task fails, re-run it
Can checkpoint RDDs to disk

Figure 5: Example of how Spark computes job stages. Boxes with solid outlines are RDDs. Partitions are shaded rectangles, in black if they are already in memory. To run an action on RDD G, we build stages at wide dependencies and pipeline narrow transformations inside each stage. In this case, stage 1's output RDD is already in RAM, so we run stage 2 and then 3.
