## Memory Management

Each operator:

- Pre-allocates heap space for input/output tuples
- Option 1: Array of pointers to base data in buffer pool
- Option 2: New tuples on the heap
- Allocates memory for its internal state
- Either on heap or in buffer pool (depends on system)

DMBS limits how much memory each operator, or each query can use

## In Flight Tuples (option 1)

Output tuple $\square$ Pre-allocated tuple descriptors, which are arrays of column references

In this example, the right tuple contains fields that themselves come from different input tuples (as a result of an earlier join)

Disk page with many ${ }_{9}$ tuples \& attributes

## In Flight Tuples (option 1)

Output tuple $\square$

## Operator

If an operator constructs a tuple descriptor referencing a tuple in buffer pool, it must increment pin count of page.
Then decrement it when descriptor is cleared.
(more details of pin count eviction policy in book)

## In Flight Tuples (option 2)

# Operator Algorithms <br> (Quick review from 344 today \& new algorithms next time) 

## Operator Algorithms

## Design criteria

- Cost: IO, CPU, Network
- Memory utilization
- Load balance (for parallel operators)

## Cost Parameters

- Cost = total number of I/Os
- This is a simplification that ignores CPU, network
- Parameters:
$-B(R)=$ \# of blocks (i.e., pages) for relation $R$
$-T(R)=\#$ of tuples in relation $R$
$-\mathbf{V}(\mathbf{R}, \mathrm{a})=$ \# of distinct values of attribute a
- When a is a key, $V(R, a)=T(R)$
- When $a$ is not a key, $V(R, a)$ can be anything $<T(R)$

## Convention

- Cost = the cost of reading operands from disk
- Cost of writing the final result to disk is not included; need to count it separately when applicable

## Outline

- Join operator algorithms

|  | - One-pass algorithms (Sec. 15.2 and 15.3) |
| :---: | :---: |
|  | rithms (Sec 15.6) |
|  | Two-pass algorithms (Sec 15.4 and 15.5) |

- Note about readings:
- In class, we discuss only algorithms for joins
- Other operators are easier: read the book

## Join Algorithms

- Hash join
- Nested loop join
- Sort-merge join

## Hash Join

Hash join: $R \bowtie S$

- Scan R, build buckets in main memory
- Then scan $S$ and join
- Cost: $B(R)+B(S)$
- One-pass algorithm when $B(R) \leq M$

## Hash Join Example

Insurance(pid, provider, policy_nb)
Patient $\bowtie$ Insurance

## Index Nested Loop Join
