

Database System Internals Optimistic Concurrency Control

Paul G. Allen School of Computer Science and Engineering University of Washington, Seattle

CSE 444 - Optimistic CC

Quizzes are cancelled this quarter

- Less cognitive load
- Hopefully gives more time to think about homework/labs

About Lab 3

In lab 3, we implement transactions

Focus on concurrency control

- Want to run many transactions at the same time
- Transactions want to read and write same pages
- Will use locks to ensure conflict serializable execution
- Use strict 2PL

Build your own lock manager

- Understand how locking works in depth
- Ensure transactions rather than threads hold locks
 - Many threads can execute different pieces of the same transaction
 - Need to detect deadlocks and resolve them by aborting a transaction
- But use Java synchronization to protect your data structures

- Several types of schedules:
 - Serializable, conflict serializable, view serializable
 - Recoverable, without cascading aborts
- PL guarantees conflict serializable schedules
- Strict 2PL also guarantees no-cascading-aborts
- Locking manager: inserts lock/unlock, manages locks
- Types of locks: shared, exclusive

Isolation Levels in SQL

- 1. "Dirty reads" SET TRANSACTION ISOLATION LEVEL READ UNCOMMITTED
- 2. "Committed reads" SET TRANSACTION ISOLATION LEVEL READ COMMITTED
- 3. "Repeatable reads" SET TRANSACTION ISOLATION LEVEL REPEATABLE READ
- 4. Serializable transactions SET TRANSACTION ISOLATION LEVEL SERIALIZABLE

1. Isolation Level: Dirty Reads

"Long duration" WRITE locks

- Strict 2PL
- No READ locks
 - Read-only transactions are never delayed

Possible problems: dirty and inconsistent reads

2. Isolation Level: Read Committed

"Long duration" WRITE locks

Strict 2PL

Short duration READ locks

Only acquire lock while reading (not 2PL)

Unrepeatable reads When reading same element twice, may get two different values

3. Isolation Level: Repeatable Read

- "Long duration" WRITE locks
 - Strict 2PL
- "Long duration" READ locks
 - Strict 2PL

This is not serializable yet !!!

4. Isolation Level Serializable

- "Long duration" WRITE locks
 - Strict 2PL
- "Long duration" READ locks
 - Strict 2PL
- Predicate locking
 - To deal with phantoms

Client 1: START TRANSACTION INSERT INTO SmallProduct(name, price) SELECT pname, price FROM Product WHERE price <= 0.99

DELETE FROM Product WHERE price <=0.99 COMMIT

Client 2: SET TRANSACTION READ ONLY START TRANSACTION SELECT count(*) FROM Product

> SELECT count(*) FROM SmallProduct COMMIT

May improve performance

Always check documentation!

- DB2: Strict 2PL
- SQL Server:
 - Strict 2PL for standard 4 levels of isolation
 - Multiversion concurrency control for snapshot isolation
- PostgreSQL: Snapshot isolation; recently: seralizable Snapshot isolation (!)
- Oracle: Snapshot isolation

Pessimistic vs. Optimistic

Pessimistic CC (locking)

- Prevents unserializable schedules
- Never abort for serializability (but may abort for deadlocks)
- Best for workloads with high levels of contention

Optimistic CC (timestamp, multi-version, validation)

- Assume schedule will be serializable
- Abort when conflicts detected
- Best for workloads with low levels of contention

Concurrency control by timestamps (18.8)

Concurrency control by validation (18.9)

Snapshot Isolation

Each transaction receives unique timestamp TS(T)

Could be:

- The system's clock
- A unique counter, incremented by the scheduler

Main invariant:

The timestamp order defines the serialization order of the transaction

Will generate a schedule that is view-equivalent to a serial schedule, and recoverable

- Scheduler receives a request, r_T(X) or w_T(X)
- Should it allow it to proceed? Wait? Abort?
- Consider these cases:

- Scheduler receives a request, r_T(X) or w_T(X)
- Should it allow it to proceed? Wait? Abort?
- Consider these cases:

- Scheduler receives a request, r_T(X) or w_T(X)
- Should it allow it to proceed? Wait? Abort?
- Consider these cases:

- Scheduler receives a request, $r_T(X)$ or $w_T(X)$
- Should it allow it to proceed? Wait? Abort?
- Consider these cases:

- Scheduler receives a request, r_T(X) or w_T(X)
- Should it allow it to proceed? Wait? Abort?
- Consider these cases:

With each element X, associate

- RT(X) = the highest timestamp of any transaction U that read X
- WT(X) = the highest timestamp of any transaction U that wrote X
- C(X) = the commit bit: true when transaction with highest timestamp that wrote X committed

With each element X, associate

- RT(X) = the highest timestamp of any transaction U that read X
- WT(X) = the highest timestamp of any transaction U that wrote X
- C(X) = the commit bit: true when transaction with highest timestamp that wrote X committed

If transactions abort, we must reset the timestamps

For any $r_T(X)$ or $w_T(X)$ request, check for conflicts:

For any $r_T(X)$ or $w_T(X)$ request, check for conflicts:

When T requests $r_T(X)$, need to check $TS(U) \le TS(T)$

Read Too Late?

T wants to read X

Read Too Late?

T wants to read X

If WT(X) > TS(T) then need to rollback T ! T tried to read **too late**

Simplified TS-based Schedule (no Aborts)

Request is r_T(X) ??

Simplified TS-based Schedule (no Aborts)

Request is r_T(X) If WT(X) > TS(T) then ROLLBACK Else READ and update RT(X) to larger of TS(T) or RT(X)

T wants to write X

START(T) ... START(U) ... $r_U(X) \dots w_T(X)$

T wants to write X

START(T) ... START(U) ... r_U(X) . . . w_T(X)

If RT(X) > TS(T) then need to rollback T ! T tried to write **too late**

Simplified TS-based Schedule (no Aborts)

Request is r_T(X) If WT(X) > TS(T) then ROLLBACK Else READ and update RT(X) to larger of TS(T) or RT(X)

Request is w_T(X) ???

Simplified TS-based Schedule (no Aborts)

Request is r_T(X) If WT(X) > TS(T) then ROLLBACK Else READ and update RT(X) to larger of TS(T) or RT(X)

Request is w_T(X) If RT(X) > TS(T) then ROLLBACK what about WT(X)? Otherwise, WRITE and update WT(X) =TS(T)

But... we can still handle it in one case:

T wants to write X

But we can still handle it:

T wants to write X

If $RT(X) \le TS(T)$ and WT(X) > TS(T)then don't write X at all ! But we can still handle it:

T wants to write X

If $RT(X) \le TS(T)$ and WT(X) > TS(T)then don't write X at all !

View serializable!

Simplified TS-based Schedule (no Aborts)

Request is r_T(X) If WT(X) > TS(T) then ROLLBACK Else READ and update RT(X) to larger of TS(T) or RT(X)

Request is w_T(X) If RT(X) > TS(T) then ROLLBACK what about WT(X)?

Otherwise, WRITE and update WT(X) =TS(T)
Simplified TS-based Schedule (no Aborts)

Request is r_T(X) If WT(X) > TS(T) then ROLLBACK Else READ and update RT(X) to larger of TS(T) or RT(X)

The simplified timestamp-based scheduling with Thomas' rule ensures that the schedule is viewserializable

Ensuring Recoverable Schedules

Recall:

- Schedule without cascading aborts: when a transaction reads an element, then transaction that wrote it must have already committed
- Use the commit bit C(X) to keep track if the transaction that last wrote X has committed (just a read will not change the commit bit)

Ensuring Recoverable Schedules

Read dirty data:

- T wants to read X, and WT(X) < TS(T)</p>
- Seems OK, but...

If C(X)=false, T needs to wait for it to become true

Ensuring Recoverable Schedules

Thomas' rule needs to be revised:

- T wants to write X, and WT(X) > TS(T)
- Seems OK not to write at all, but ...

If C(X)=false, T needs to wait for it to become true

- When a transaction T requests r_T(X) or w_T(X), the scheduler examines RT(X), WT(X), C(X), and decides one of:
- To grant the request, or
- To rollback T (and restart with later timestamp)
- To delay T until C(X) = true

Timestamp-based Scheduling

RULES including commit bit

- There are 4 long rules in Sec. 18.8.4
- You should be able to derive them yourself, based on the previous slides
- Make sure you understand them !

READING ASSIGNMENT:

Garcia-Molina et al. 18.8.4

Timestamp-based Scheduling (sec. 18.8.4)

Transaction wants to READ element X If WT(X) > TS(T) then ROLLBACK Else If C(X) = false, then WAIT Else READ and update RT(X) to larger of TS(T) or RT(X)

Transaction wants to WRITE element X If RT(X) > TS(T) then ROLLBACK Else if WT(X) > TS(T) Then If C(X) = false then WAIT else IGNORE write (Thomas Write Rule) Otherwise, WRITE, and update WT(X)=TS(T), C(X)=false

Summary of Timestamp-based Scheduling

- View-serializable
- Avoids cascading aborts (hence: recoverable)
- Does NOT handle phantoms
 - These need to be handled separately, e.g. predicate locks

- When transaction T requests r(X) but WT(X) > TS(T), then T must rollback
- Idea: keep multiple versions of X: X_t, X_{t-1}, X_{t-2}, . . .

 $TS(X_t) > TS(X_{t-1}) > TS(X_{t-2}) > ...$

TS(T)=6 X_3 X_9 X_{12} X_{18} $R_6(X)$ -- what happens? $W_{14}(X)$ – what happens? $R_{15}(X)$ – what happens? $W_5(X)$ – what happens?

TS(T)=6 X_3 X_9 X_{12} X_{18} $R_6(X)$ -- what happens? Return X_3 $W_{14}(X)$ - what happens? $R_{15}(X)$ - what happens? $W_5(X)$ - what happens?

 X_3

TS(T)=6

$R_6(X)$ -- what happens? Return X_3 $W_{14}(X)$ – what happens? $R_{15}(X)$ – what happens? $W_5(X)$ – what happens?

Xq

X₁₂

 X_{18}

 X_3

TS(T)=6

$R_6(X)$ -- what happens? Return X_3 $W_{14}(X)$ – what happens? $R_{15}(X)$ – what happens? $W_5(X)$ – what happens?

 $X_9 X_{12} X_{14} X_{18}$

 X_3

TS(T)=6

 $R_6(X)$ -- what happens? Return X_3 $W_{14}(X)$ – what happens? $R_{15}(X)$ – what happens? $W_5(X)$ – what happens?

 $X_9 X_{12} X_{14} X_{18}$

TS(T)=6 X_3 X_9 X_{12} X_{14} X_{18} $R_6(X)$ -- what happens? Return X_3 $W_{14}(X)$ – what happens? Return X_{14} $R_{15}(X)$ – what happens? Return X_{14} $W_5(X)$ – what happens?

TS(T)=6 X_3 X_9 X_{12} X_{14} X_{18} $R_6(X)$ -- what happens? Return X_3 $W_{14}(X)$ -- what happens? $R_{15}(X)$ -- what happens? Return X_{14} $W_5(X)$ -- what happens?
Example (in class)

TS(T)=6 X_3 X_9 X_{12} X_{14} X_{18} $R_6(X)$ -- what happens? Return X_3 $W_{14}(X)$ – what happens? Return X_{14} $R_{15}(X)$ – what happens? Return X_{14} $W_5(X)$ – what happens? ABORT

When can we delete X₃?

TS(T)=6

 $R_6(X)$ -- what happens? Return X_3 $W_{14}(X)$ – what happens? $R_{15}(X)$ – what happens? Return X_{14} $W_5(X)$ – what happens? ABORT

 $X_3 \qquad X_9 \qquad X_{12} \qquad X_{14} \qquad X_{18}$

When can we delete X_3 ?

TS(T)=6 X_3 X_9 X_{12} X_{14} X_{18} $R_6(X)$ -- what happens? Return X_3 $W_{14}(X)$ -- what happens? $R_{15}(X)$ -- what happens? Return X_{14} $W_5(X)$ -- what happens? ABORT

When can we delete X_3 ? When min TS(T)> 9

Details

- When w_T(X) occurs,
 - if the write is legal then

create a new version, denoted X_t where t = TS(T)

Details

When w_T(X) occurs,

if the write is legal then

create a new version, denoted X_t where t = TS(T)

- When r_T(X) occurs, find most recent version X_t such that t <= TS(T) Notes:
 - $WT(X_t) = t$ and it never changes for that version
 - RT(X_t) must still be maintained to check legality of writes

Details

When w_T(X) occurs,

if the write is legal then

create a new version, denoted X_t where t = TS(T)

- When r_T(X) occurs, find most recent version X_t such that t <= TS(T) Notes:
 - $WT(X_t) = t$ and it never changes for that version
 - RT(X_t) must still be maintained to check legality of writes keep only the largest value
- Can delete X_t if we have a later version X_{t1} and all active transactions T have TS(T) > t1

Example w/ Basic Timestamps

	T ₁	T_2	T_3	T ₄	А
Timestamps:	1	2	3	4	RT=0
					WT=0
	R ₁ (A)				RT=1
	W ₁ (A)				WT=1
	· · · · · · · · · · · · · · · · · · ·		$R_3(A)$		RT=3
			$W_3(A)$		WT=3
		$R_2(A)$			
		Abort			
				$R_4(A)$	RT=4

Second Example w/ Multiversion

T ₁	T ₂	T_3	T ₄	T_5	A_0	A ₁	A_2	A_3	A_4	A_5
1	2	3	4	5						
			$W_4(A)$							

Second Example w/ Multiversion

Multiversion Concurrency Control

- View serializable
- Avoids cascading aborts
- Handles phantoms correctly

Outline

- Concurrency control by timestamps (18.8)
- Concurrency control by validation (18.9)
- Snapshot Isolation

Concurrency Control by Validation

Each transaction T defines:

- Read set RS(T) = the elements it reads
- Write set WS(T) = the elements it writes
- Each transaction T has three phases:
 - Read phase; time = START(T)
 - Validate phase (may need to rollback); time = VAL(T)
 - Write phase; time = FIN(T)

Main invariant: the serialization order is VAL(T)

Avoid $r_T(X) - w_U(X)$ Conflicts

IF RS(T) ∩ WS(U) and FIN(U) > START(T)
 (U has validated and U has not finished before T begun)
Then ROLLBACK(T)

Avoid $w_T(X) - w_U(X)$ Conflicts

IF WS(T) ∩ WS(U) and FIN(U) > VAL(T)
 (U has validated and U has not finished before T validates)
Then ROLLBACK(T)

Outline

- Concurrency control by timestamps (18.8)
- Concurrency control by validation (18.9)
- Snapshot Isolation
 - Not in the book, but good(?) overview in Wikipedia

Snapshot Isolation

- A type of multiversion concurrency control algorithm
- Combines techniques we learned:
 - Timestamps
 - Multiversion
 - Validation
- Very popular: Oracle, PostgreSQL, SQL Server 2005
- Prevents many classical anomalies BUT...
 ...not serializable (!)
- "Serializable snapshot isolation" now in PostgreSQL

Snapshot Isolation Overview

- Each transactions receives a timestamp TS(T)
- Transaction T sees snapshot at time TS(T) of the database
- W/W conflicts resolved by "first committer wins" rule
 Loser gets aborted
- R/W conflicts are ignored

Snapshot Isolation Details

- Multiversion concurrency control:
 - Versions of X: X_{t1} , X_{t2} , X_{t3} , ...
- When T reads X, return X_{TS(T)}.
- When T writes X (to avoid lost update):
 - If latest version of X is TS(T) then proceed
 - Else if C(X) = true then abort
 - Else if C(X) = false then wait
- When T commits, write its updates to disk

What Works and What Not

- Reads are ever delayed!
- No dirty reads (Why ?)
 - Start each snapshot with consistent state
- No inconsistent reads (Why ?)
 - Two reads by the same transaction will read same snapshot
- No lost updates ("first committer wins")
- However: read-write conflicts not caught!
 - A txn can read and commit even though the value had changed in the middle

In our notation:

$$R_1(X), R_2(Y), W_1(Y), W_2(X), C_1, C_2$$

Starting with X=50,Y=50, we end with X=-50, Y=-50. Non-serializable !!!

Write Skews Can Be Serious

- Acidicland had two viceroys, Delta and Rho
- Budget had two registers: taXes, and spendYng
- They had high taxes and low spending...

```
Delta:

READ(taXes);

if taXes = 'High'

then { spendYng = 'Raise';

WRITE(spendYng) }

COMMIT
```

```
Rho:
READ(spendYng);
if spendYng = 'Low'
then {taXes = 'Cut';
WRITE(taXes) }
COMMIT
```

... and they ran a deficit ever since.

Discussion: Tradeoffs

Pessimistic CC: Locks

- Great when there are many conflicts
- Poor when there are few conflicts
- Optimistic CC: Timestamps, Validation, SI
 - Poor when there are many conflicts (rollbacks)
 - Great when there are few conflicts

Compromise

- READ ONLY transactions \rightarrow timestamps
- READ/WRITE transactions \rightarrow locks
Always check documentation!

- DB2: Strict 2PL
- SQL Server:
 - Strict 2PL for standard 4 levels of isolation
 - Multiversion concurrency control for snapshot isolation
- PostgreSQL: SI; recently: seralizable SI (!)
- Oracle: SI
