

Database System Internals Concurrency Control - Locking

Paul G. Allen School of Computer Science and Engineering University of Washington, Seattle

Serializability

- Serial
- Serializable
- Conflict serializable
- View serializable

Recoverability

- Recoverable
- Avoids cascading deletes

Scheduler

- The scheduler:
- Module that schedules the transaction's actions, ensuring serializability
- Two main approaches
- Pessimistic: locks
- Optimistic: timestamps, multi-version, validation

Pessimistic Scheduler

Simple idea:

- Each element has a unique lock
- Each transaction must first acquire the lock before reading/writing that element
- If the lock is taken by another transaction, then wait
- The transaction must release the lock(s)

Notation

 $L_i(A)$ = transaction T_i acquires lock for element A

 $U_i(A)$ = transaction T_i releases lock for element A

A Non-Serializable Schedule

```
T2
READ(A, t)
t := t + 100
WRITE(A, t)
                 READ(A,s)
                 s := s*2
                 WRITE(A,s)
                 READ(B,s)
                 s := s*2
                 WRITE(B,s)
READ(B, t)
t := t + 100
WRITE(B,t)
```

Example

```
T1
                                 T2
L_1(A); READ(A, t)
t := t + 100
WRITE(A, t); U_1(A); L_1(B)
                                 L_2(A); READ(A,s)
                                 s := s*2
                                 WRITE(A,s); U_2(A);
                                 L_2(B); DENIED...
READ(B, t)
t := t + 100
WRITE(B,t); U_1(B);
                                 ...GRANTED; READ(B,s)
                                 s := s*2
                                 WRITE(B,s); U_2(B);
```

Scheduler has ensured a conflict-serializable schedule

15

```
T1
                               T2
L_1(A); READ(A, t)
t := t + 100
WRITE(A, t); U_1(A);
                              L_2(A); READ(A,s)
                              s := s*2
                              WRITE(A,s); U_2(A);
                              L_2(B); READ(B,s)
                              s := s*2
                              WRITE(B,s); U_2(B);
L_1(B); READ(B, t)
t := t + 100
WRITE(B,t); U_1(B);
```

Locks did not enforce conflict-serializability !!! What's wrong?

The 2PL rule:

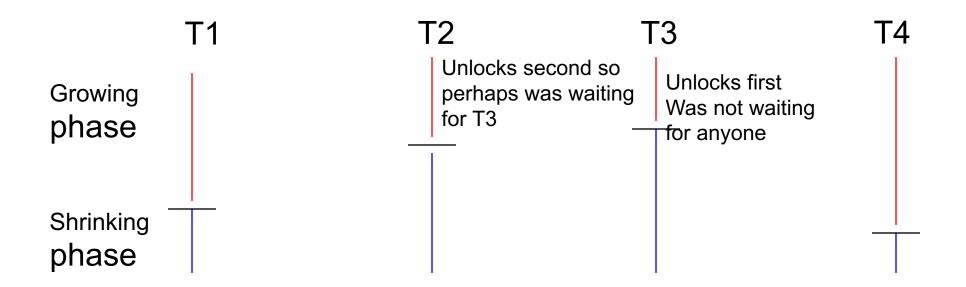

In every transaction, all lock requests must precede all unlock requests

This ensures conflict serializability! (will prove this shortly)

Example: 2PL transactions

```
T2
  T1
 L_1(A); L_1(B); READ(A, t)
  t := t + 100
  WRITE(A, t); U_1(A)
                                   L_2(A); READ(A,s)
                                   s := s*2
                                   WRITE(A,s);
                                   L_2(B); DENIED...
  READ(B, t)
  t := t + 100
  WRITE(B,t); U_1(B);
                                   ...GRANTED; READ(B,s)
                                   s := s*2
                                   WRITE(B,s); U_2(A); U_2(B);
Now it is conflict-serializable
```

Example with Multiple Transactions

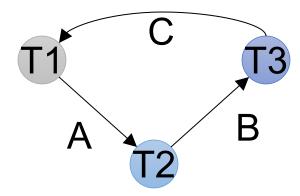

Equivalent to each transaction executing entirely the moment it enters shrinking phase

Theorem: 2PL ensures conflict serializability

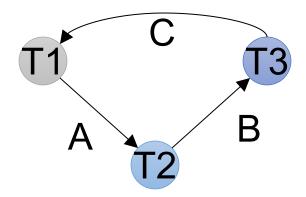

Theorem: 2PL ensures conflict serializability

Proof. Suppose not: then there exists a cycle in the precedence graph.

Theorem: 2PL ensures conflict serializability

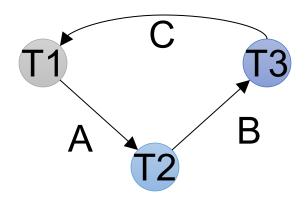

Proof. Suppose not: then there exists a cycle in the precedence graph.

Then there is the following **temporal** cycle in the schedule:

Theorem: 2PL ensures conflict serializability

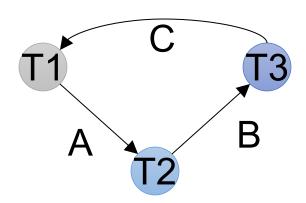

Proof. Suppose not: then there exists a cycle in the precedence graph.

Then there is the following <u>temporal</u> cycle in the schedule: $U_1(A) \rightarrow L_2(A)$ why?

Theorem: 2PL ensures conflict serializability

Proof. Suppose not: then there exists a cycle in the precedence graph.

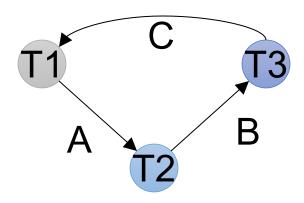

Then there is the following <u>temporal</u> cycle in the schedule:

$$U_1(A) \rightarrow L_2(A)$$

 $L_2(A) \rightarrow U_2(B)$ why?

Theorem: 2PL ensures conflict serializability

Proof. Suppose not: then there exists a cycle in the precedence graph.

Then there is the following temporal cycle in the schedule:

$$U_{1}(A) \rightarrow L_{2}(A)$$

$$L_{2}(A) \rightarrow U_{2}(B)$$

$$U_{2}(B) \rightarrow L_{3}(B)$$

$$L_{3}(B) \rightarrow U_{3}(C)$$

$$U_{3}(C) \rightarrow L_{1}(C)$$

$$L_{1}(C) \rightarrow U_{1}(A)$$
Contradiction

A New Problem:

```
T1
                                       T2
L_1(A); L_1(B); READ(A, t)
t := t + 100
WRITE(A, t); U_1(A)
                                       L_2(A); READ(A,s)
                                       s := s*2
                                       WRITE(A,s);
                                       L<sub>2</sub>(B); DENIED...
READ(B, t)
t := t + 100
WRITE(B,t); U_1(B);
                                       ...GRANTED; READ(B,s)
                                       s := s*2
                                       WRITE(B,s); U_2(A); U_2(B);
                                       Commit
Abort
```

Strict 2PL

- Strict 2PL: All locks held by a transaction are released when the transaction is completed; release happens at the time of COMMIT or ROLLBACK
- Schedule is recoverable
- Schedule avoids cascading aborts

```
T1
                                            T2
L<sub>1</sub>(A); READ(A)
A := A + 100
WRITE(A);
                                            L<sub>2</sub>(A); DENIED...
L_1(B); READ(B)
B := B + 100
WRITE(B);
U_1(A), U_1(B); Rollback
                                             ...GRANTED; READ(A)
                                            A := A*2
                                            WRITE(A);
                                            L_2(B); READ(B)
                                            B := B*2
                                            WRITE(B);
                                            U_2(A); U_2(B); Commit
                   CSE 444 - Spring 2021
```

Terminology Needed For Lab 3

STEAL or NO-STEAL

When can we evict dirty pages from the buffer pool?

FORCE or NO-FORCE

 When do we need to synchronize updates made by a transaction relative to commit time?

Terminology Needed For Lab 3

STEAL or NO-STEAL

When can we evict dirty pages from the buffer pool?

FORCE or NO-FORCE

- When do we need to synchronize updates made by a transaction relative to commit time?
- Easiest for recovery: NO-STEAL/FORCE (lab 3)

Summary of Strict 2PL

 Ensures serializability, recoverability, and avoids cascading aborts

Issues?

Summary of Strict 2PL

- Ensures serializability, recoverability, and avoids cascading aborts
- Issues: implementation, lock modes, granularity, deadlocks, performance

The Locking Scheduler

Task 1: -- act on behalf of the transaction

Add lock/unlock requests to transactions

- Examine all READ(A) or WRITE(A) actions
- Add appropriate lock requests
- On COMMIT/ROLLBACK release all locks
- Ensures Strict 2PL!

The Locking Scheduler

Task 2: -- act on behalf of the system Execute the locks accordingly

- Lock table: a big, critical data structure in a DBMS!
- When a lock is requested, check the lock table
 - Grant, or add the transaction to the element's wait list
- When a lock is released, re-activate a transaction from its wait list
- When a transaction aborts, release all its locks
- Check for deadlocks occasionally

Lock Modes

- S = shared lock (for READ)
- X = exclusive lock (for WRITE)

Lock compatibility matrix:

None S X

None	S	X
OK	OK	OK
OK	OK	Conflict
OK	Conflict	Conflict

Lock Granularity

- Fine granularity locking (e.g., tuples)
 - •
 - •
- Coarse grain locking (e.g., tables, predicate locks)
 - •
 - •

Lock Granularity

- Fine granularity locking (e.g., tuples)
 - High concurrency
 - High overhead in managing locks
- Coarse grain locking (e.g., tables, predicate locks)
 - •
 - •

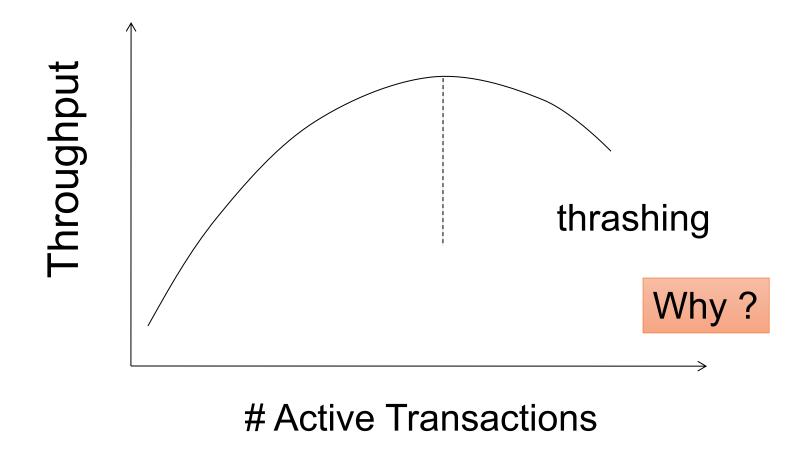

Lock Granularity

- Fine granularity locking (e.g., tuples)
 - High concurrency
 - High overhead in managing locks
- Coarse grain locking (e.g., tables, predicate locks)
 - Many false conflicts
 - Less overhead in managing locks

Deadlocks

- Cycle in the wait-for graph:
 - T1 waits for T2
 - T2 waits for T3
 - T3 waits for T1
- Deadlock detection
 - Timeouts
 - Wait-for graph
- Deadlock avoidance
 - Acquire locks in pre-defined order
 - Acquire all locks at once before starting

Lock Performance

 So far we have assumed the database to be a static collection of elements (=tuples)

If tuples are inserted/deleted then the phantom problem appears

T1 T2

SELECT *
FROM Product
WHERE color='blue'

INSERT INTO Product(name, color) VALUES ('gizmo', 'blue')

SELECT *
FROM Product
WHERE color='blue'

Is this schedule serializable?

T1 T2

SELECT *
FROM Product
WHERE color='blue'

INSERT INTO Product(name, color)

VALUES ('gizmo', 'blue')

SELECT *
FROM Product
WHERE color='blue'

Suppose there are two blue products, X1, X2:

R1(X1),R1(X2),W2(X3),R1(X1),R1(X2),R1(X3)

T1 T2

SELECT *
FROM Product
WHERE color='blue'

INSERT INTO Product(name, color) VALUES ('gizmo', 'blue')

SELECT *
FROM Product
WHERE color='blue'

Suppose there are two blue products, X1, X2:

R1(X1),R1(X2),W2(X3),R1(X1),R1(X2),R1(X3)

This is conflict serializable! What's wrong??

T1 T2

SELECT *
FROM Product
WHERE color='blue'

INSERT INTO Product(name, color) VALUES ('gizmo', 'blue')

SELECT *
FROM Product
WHERE color='blue'

Suppose there are two blue products, X1, X2:

R1(X1),R1(X2),W2(X3),R1(X1),R1(X2),R1(X3)

Not serializable due to *phantoms*

 A "phantom" is a tuple that is invisible during part of a transaction execution but not invisible during the entire execution

- In our example:
 - T1: reads list of products
 - T2: inserts a new product
 - T1: re-reads: a new product appears!

- In a <u>static</u> database:
 - Conflict serializability implies serializability
- In a <u>dynamic</u> database, this may fail due to phantoms
- Strict 2PL guarantees conflict serializability, but not serializability

Dealing With Phantoms

- Lock the entire table, or
- Lock the index entry for 'blue'
 - If index is available
- Or use predicate locks
 - A lock on an arbitrary predicate

Dealing with phantoms is expensive!

Isolation Levels in SQL

- 1. "Dirty reads"
 SET TRANSACTION ISOLATION LEVEL READ UNCOMMITTED
- 2. "Committed reads"

 SET TRANSACTION ISOLATION LEVEL READ COMMITTED
- 3. "Repeatable reads"

 SET TRANSACTION ISOLATION LEVEL REPEATABLE READ
- 4. Serializable transactions
 SET TRANSACTION ISOLATION LEVEL SERIALIZABLE

ACID

1. Isolation Level: Dirty Reads

- "Long duration" WRITE locks
 - Strict 2PL
- No READ locks
 - Read-only transactions are never delayed

Possible problems: dirty and inconsistent reads

2. Isolation Level: Read Committed

- "Long duration" WRITE locks
 - Strict 2PL
- "Short duration" READ locks
 - Only acquire lock while reading (not 2PL)

Unrepeatable reads
When reading same element twice,
may get two different values

3. Isolation Level: Repeatable Read

- "Long duration" WRITE locks
 - Strict 2PL
- "Long duration" READ locks
 - Strict 2PL

This is not serializable yet !!!

4. Isolation Level Serializable

- "Long duration" WRITE locks
 - Strict 2PL
- "Long duration" READ locks
 - Strict 2PL
- Predicate locking
 - To deal with phantoms

READ-ONLY Transactions

```
Client 1: START TRANSACTION
   INSERT INTO SmallProduct(name, price)
       SELECT pname, price
       FROM Product
       WHERE price <= 0.99
   DELETE FROM Product
        WHERE price <= 0.99
   COMMIT
Client 2: SET TRANSACTION READ ONLY
   START TRANSACTION
   SELECT count(*)
   FROM Product
   SELECT count(*)
   FROM SmallProduct
   COMMIT
```

May improve performance

February 9, 2022

Commercial Systems

Always check documentation!

- DB2: Strict 2PL
- SQL Server:
 - Strict 2PL for standard 4 levels of isolation
 - Multiversion concurrency control for snapshot isolation
- PostgreSQL: Snapshot isolation; recently: seralizable Snapshot isolation (!)
- Oracle: Snapshot isolation
