D-1

Structured Query Language

- Started as "Sequel"
- Now an ANSI (X3H2) / ISO standard
 - SQL2 or SQL-92
 - SQL3 is in the works
- Lots of uses and versions
 - As a direct language our focus
 - As an embedded language in a program in a conventional language
 - As a protocol from client to DB server increasingly important

10/21/97

E-2

SQL DDL

- TABLE/SCHEMA/CATALOG
- CREATE/DROP/ALTER
- SQL DATA TYPES
 - DB files are often character-based, descended from COBOL
 - INT, FLOAT, etc.
 - DEC(i,j)
 - CHAR(n), VARCHAR(n)
 - DATE/TIME

10/21/97

E-3

90% of what you need to know

SELECT <attributes>

FROM <tables>

WHERE <conditions>

- SELECT is a projection into the output
- FROM is effectively a Cartesian product of all the tables used
- WHERE are conditions, which could be very elaborate and even involve nested SELECTs.

10/21/97

E-4

Some Notation

- Attributes can be qualified
 - Tables can be renamed
- ```
SELECT S.FNAME, S.LNAME
FROM EMPLOYEE E, EMPLOYEE S
WHERE E.SUPERSSN = S.ESSN
```
- *SELECT* \* means display all columns
  - No *WHERE* means display all rows

10/21/97

E-5

## More SQL Topics

- Conditionals
  - NOT, AND, OR (in precedence order)
- Tables vs sets
  - Duplicates are NOT eliminated on most operations!
  - DISTINCT keyword eliminates dups in SELECT

10/21/97

E-6

## Set Operations

- UNION, intersections ("INTERSECT"), difference ("EXCEPT")
  - DO eliminate duplicates
  - Use to connect whole sets (result of queries), not within WHERE
  - EXCEPT not supported by MS Access 97
- Division is not an SQL operation
- Older SQL had a CONTAINS (set inclusion)

10/21/97

E-7

## IN and EXISTS

- IN
  - Tests for membership in a set:  $x \in A$
  - Binary operator returning Boolean value
    - used within conditions (WHERE)
    - left side a row (or value construed as a row)
    - right side a table, frequently the result of a (nested) SELECT
- EXISTS
  - Unary operator returning a Boolean
  - tests a table for non-empty:  $A \neq \emptyset$

10/21/97

E-8

## Aggregate Functions

- Five standard functions: COUNT, SUM, MIN, MAX, AVG
- Normally appears in SELECT clause  
SELECT SUM (SALARY)
- Is applied after WHERE
- Result is a column in the output
  - can sometimes think of as a scalar

10/21/97

E-9

## Grouping

- GROUP BY <attributes>
  - causes rows with common values to be grouped together
  - no particular ordering among groups
- Might be used just to improve output presentation, but...
- Most commonly used in connection with aggregate functions

10/21/97

E-10

## Grouping and Functions

***In presence of grouping, aggregate functions apply to each group individually.***

- Output has one row per group
- Order of processing: WHERE conditions, then GROUPING, then SELECT (including agg. functions).
  - What if you want a condition applied after the grouping??

10/21/97

E-11

## HAVING

- Applies a condition after grouping
  - condition is applied to each group
- May use aggregate functions
  - HAVING SUM(QUANTITY) > 350

10/21/97

E-12
