Remember:

HW1 due  
next week.

# Review

## Danger: Overfitting

# Estimating your Error and Some help in avoiding overfitting

- ▶ Test set: use these to estimate the performance of your learning algorithm.  
The cardinal rule of machine learning: **Don't touch your test data.**
- ▶ Dev set: use this during learning to help avoid overfitting.  
If we have **hyperparameters** (like depth, width), we can **tune** these on **development data**.

## One limit of learning: Inductive Bias

- ▶ Just as *you* had a tendency to focus on a certain type of function  $f$ , you want your algorithm to be “biased” towards the correct classifier (so that it can learn with a “small” number of examples).
- ▶ BUT remember there is “no free lunch”: this “bias” means you must do worse on other (hopefully unrealistic) problems.

## Another Limit of Learning: The Bayes Optimal Classifier

$$f^{(\text{BO})}(x) = \underset{y \in \{0,1\}}{\operatorname{argmax}} \mathcal{D}(x, y)$$

$P_{\pi}(x, y)$

**Theorem:** The Bayes optimal classifier achieves minimal expected classification (e.g. zero/one) error ( $\ell(y, \hat{y}) = \mathbb{I}[y \neq \hat{y}]$ ) of any deterministic classifier.

See CIML and lecture notes for proof.

25.0	4	110.0	87.00	2672.	17.5	70	2
24.0	4	107.0	90.00	2430.	14.5	70	2

- ▶ All features are really represented as real values. (they are really “tuples”)
- ▶ The “1–2–3” values suggest ordinality, which is misleading.
- ▶ Side note: can convert discrete origin feature into three binary features as follows:

1/america  $\rightarrow (1, 0, 0)$

2/europe  $\rightarrow (0, 1, 0)$

3/asia  $\rightarrow (0, 0, 1)$

## Instance $x$ Becomes Vector $x$

First example in the data, “Chevrolet Chevelle Malibu,” becomes:

[8, 307.0, 130.0, 3504, 12.0, 70, 1, 0, 0]

“Buick Skylark 320” becomes:

[8, 350.0, 165.0, 3693, 11.5, 70, 1, 0, 0]

## Euclidean Distance

$$\mathbf{x} = (x[1], x[2], \dots, x[d])$$
$$\mathbf{x}' = \dots$$

General formula for the Euclidean distance between two  $d$ -length vectors:

$$\begin{aligned} \text{dist}(\mathbf{x}, \mathbf{x}') &= \sqrt{\sum_{j=1}^d (\mathbf{x}[j] - \mathbf{x}'[j])^2} \\ &= \|\mathbf{x} - \mathbf{x}'\|_2 \end{aligned}$$

The distance between the Chevrolet Chevelle Malibu and the Buick Skylark 320:

$$\begin{aligned} &\sqrt{(8 - 8)^2 + (307 - 350)^2 + (130 - 165)^2 + (3504 - 3693)^2} \\ &\quad + (12 - 11.5)^2 + (70 - 70)^2 + (1 - 1)^2 + (0 - 0)^2 + (0 - 0)^2 \\ &= \sqrt{1849 + 1225 + 35721 + 0.25} \\ &\approx 196.965 \end{aligned}$$

## Training Data in $\mathbb{R}^d$

## Classifying a New Example in $\mathbb{R}^d$

# Nearest Neighbor Classifier

label  $x$  with the  
same label as its

**Data:** training data  $D = \langle (\mathbf{x}_n, y_n) \rangle_{n=1}^N$ , input  $\mathbf{x}$

**Result:** predicted class

let  $n^* = \operatorname{argmin}_{n \in \{1, \dots, N\}} \operatorname{dist}(\mathbf{x}_n, \mathbf{x});$

return  $y_{n^*};$

nearest training  
input

**Algorithm 1:** NNTEST

## Concept: Decision Boundary

## Concept: Decision Boundary

## Classifying a New Example in $\mathbb{R}^d$

# K-Nearest Neighbors Classifier

**Data:** training data  $D = \langle (\mathbf{x}_n, y_n) \rangle_{n=1}^N$ , input  $\mathbf{x}$

**Result:** predicted class

$S = \emptyset$ ;

**for**  $n \in \{1, \dots, N\}$  **do**

$S = S \cup \{(\text{dist}(\mathbf{x}_n, \mathbf{x}), y_n)\}$ ;

**end**

# sort on distances

$L = \text{SORT}(S)$ ;

return MAJORITYCLASS( $L[1], \dots, L[K]$ );

**Algorithm 2:** KNNTEST

classify  $x$   
based on the  
majority vote of ~~the~~  
 $x$ 's nearest neighbors

## $K$ -Nearest Neighbors: Comments

- ▶ Inductive Bias:
  - ▶ Neighbors have the same label; classes align to contiguous “regions” in feature space.
  - ▶ All features are equally important.
- ▶ What is the training error of 1-NN? ①
- ▶ Should  $K$  be even or odd? odd
- ▶ What about high dimensions? ← *curse of dimensionality*

## Detour: Unsupervised Learning

# Unsupervised Learning

The training dataset consists only of  $\langle \mathbf{x}_n \rangle_{n=1}^N$ .

There might, or might not, be a test set with correct classes  $y$ .

Simplest kind of unsupervised learning: cluster into  $K$  groups.

# How should we cluster the points?

“chicken-egg” problem:

- ▶ If we know which points are grouped together, then easy to figure out the mean of any cluster.
- ▶ If we know the means of the clusters, then easy to group the points together.

How do we cluster our points?

# An Iterative Clustering Algorithm

*k-means*

# An Iterative Clustering Algorithm

The stars are **cluster centers**, randomly initialized.

# An Iterative Clustering Algorithm

Assign each example to its nearest cluster center.

# An Iterative Clustering Algorithm

Recalculate cluster centers to reflect their respective examples.

# An Iterative Clustering Algorithm

Assign each example to its nearest cluster center.

# An Iterative Clustering Algorithm

Recalculate cluster centers to reflect their respective examples.

# An Iterative Clustering Algorithm

Assign each example to its nearest cluster center.

# An Iterative Clustering Algorithm

Recalculate cluster centers to reflect their respective examples.

# An Iterative Clustering Algorithm

$\frac{1}{\text{\# blue points } i} \sum \bar{x}_i$

① here is a "cost" to a configuration

② K-means decreases this cost

At this point, nothing will change;  
we have converged.
