CSE 451: Operating Systems Winter 2001

Lecture 8
Semaphores and Monitors

Semaphores

- semaphore = a synchronization primitive
 - higher level than locks
 - invented by Dijkstra in 1968, as part of the THE os
- A semaphore is:
 - a variable that is manipulated atomically through two operations, signal and wait
 - wait(semaphore): decrement, block until semaphore is open
 - also called P(), after Dutch word for test, also called down()
 - signal(semaphore): increment, allow another to enter
 - also called V(), after Dutch word for increment, also called up()

Blocking in Semaphores

- Each semaphore has an associated queue of processes/threads
 - when wait() is called by a thread,
 - if semaphore is "open", thread continues
 - if semaphore is "closed", thread blocks, waits on queue
 - signal() opens the semaphore
 - if thread(s) are waiting on a queue, one thread is unblocked
 - if no threads are on the queue, the signal is remembered for next time a wait() is called
- In other words, semaphore has history
 - this history is a counter
 - if counter falls below 0 (after decrement), then the semaphore is closed
 - wait decrements counter
 - signal increments counter

Hypothetical Implementation

```
type semaphore = record
   value: integer:
   L: list of processes;
end
wait(S):
   S.value = S.value - 1;
   if S.value < 0
   then begin
                                                            wait()/signal() are
         add this process to S.L;
         block;
                                                             critical sections!
         end:
                                                          Hence, they must be
                                                          executed atomically
signal(S):
                                                          with respect to each
   S.value = S.value + 1:
   if S.value <= 0
                                                                  other.
   then begin
         remove a process P from S.L;
         wakeup P
         end;
```

Two types of semaphores

- Binary semaphore (aka mutex semaphore)
 - guarantees mutually exclusive access to resource
 - only one thread/process allowed entry at a time
 - counter is initialized to 1
- Counting semaphore (aka counted semaphore)
 - represents a resources with many units available
 - allows threads/process to enter as long as more units are available
 - counter is initialized to N
 - N = number of units available

Example: bounded buffer problem

- AKA producer/consumer problem
 - there is a buffer in memory
 - with finite size N entries
 - a producer process inserts an entry into it
 - a consumer process removes an entry from it
- Processes are concurrent
 - so, we must use synchronization constructs to control access to shared variables describing buffer state

Bounded Buffer using Semaphores

```
:mutual exclusion to shared data
var mutex: semaphore = 1
   empty: semaphore = n
                            count of empty buffers (all empty to start)
                            ;count of full buffers (none full to start)
   full: semaphore = 0
producer:
   wait(empty)
                 ; one fewer buffer, block if none available
   wait(mutex) ; get access to pointers
         <add item to buffer>
   signal(mutex); done with pointers
   signal(full); note one more full buffer
consumer:
   wait(full) ;wait until there's a full buffer
   wait(mutex) ; get access to pointers
         <remove item from buffer>
   signal(mutex); done with pointers
   signal(empty); note there's an empty buffer
         <use the item>
```

Example: Readers/Writers

- Basic problem:
 - object is shared among several processes
 - some read from it
 - others write to it
- We can allow multiple readers at a time
 - why?
- We can only allow one writer at a time
 - why?

Readers/Writers using Semaphores

```
var mutex: semaphore
                             : controls access to readcount
   wrt: semaphore; control entry to a writer or first reader
   readcount: integer ; number of readers
write process:
   wait(wrt)
               ; any writers or readers?
     <perform write operation>
   signal(wrt)
                   ; allow others
read process:
   wait(mutex)
                   ; ensure exclusion
         readcount = readcount + 1; one more reader
         if readcount = 1 then wait(wrt); if we're the first, synch with writers
   signal(mutex)
         <perform reading>
   wait(mutex) ; ensure exclusion
         readcount = readcount - 1; one fewer reader
         if readcount = 0 then signal(wrt); no more readers, allow a writer
   signal(mutex)
```

Readers/Writers notes

Note:

- the first reader blocks if there is a writer
 - any other readers will then block on mutex
- if a writer exists, last reader to exit signals waiting writer
 - can new readers get in while writer is waiting?
- when writer exits, if there is both a reader and writer waiting,
 which one goes next is up to scheduler

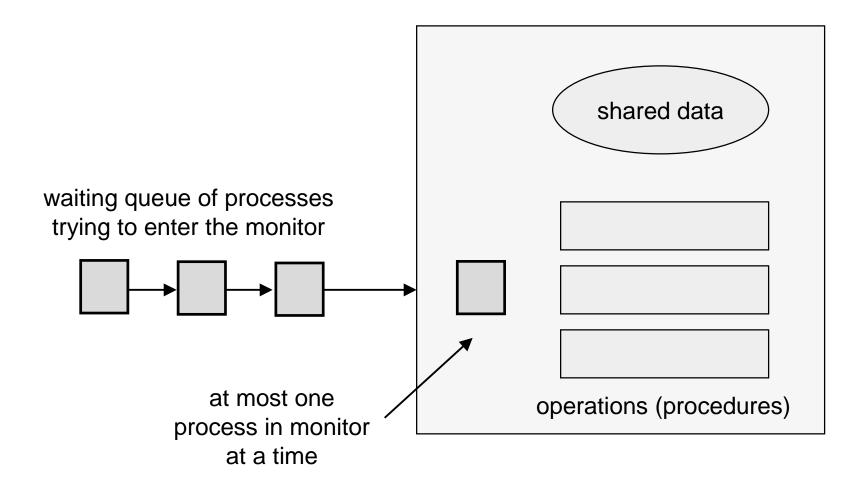

Problems with Semaphores

- They can be used to solve any of the traditional synchronization problems, but:
 - semaphores are essentially shared global variables
 - can be accessed from anywhere (bad software engineering)
 - there is no connection between the semaphore and the data being controlled by it
 - used for both critical sections (mutual exclusion) and for coordination (scheduling)
 - no control over their use, no guarantee of proper usage
- Thus, they are prone to bugs
 - another (better?) approach: use programming language support

Monitors

- A programming language construct that supports controlled access to shared data
 - synchronization code added by compiler, enforced at runtime
 - why does this help?
- Monitor is a software module that encapsulates:
 - shared data structures
 - procedures that operate on the shared data
 - synchronization between concurrent processes that invoke those procedures
- Monitor protects the data from unstructured access
 - guarantees only access data through procedures, hence in legitimate ways

A monitor

Monitor facilities

- Mutual exclusion
 - only one process can be executing inside at any time
 - thus, synchronization implicitly associated with monitor
 - if a second process tries to enter a monitor procedure, it blocks until the first has left the monitor
 - more restrictive than semaphores!
 - but easier to use most of the time
- Once inside, a process may discover it can't continue, and may wish to sleep
 - or, allow some other waiting process to continue
 - condition variables provided within monitor
 - processes can wait or signal others to continue
 - condition variable can only be accessed from inside monitor

Condition Variables

- A place to wait; sometimes called a rendezvous point
- Three operations on condition variables
 - wait(c)
 - release monitor lock, so somebody else can get in
 - wait for somebody else to signal condition
 - thus, condition variables have wait queues
 - signal(c)
 - wake up at most one waiting process/thread
 - if no waiting processes, signal is lost
 - this is different than semaphores: no history!
 - broadcast(c)
 - wake up all waiting processes/threads

Bounded Buffer using Monitors

```
Monitor bounded_buffer {
 buffer resources[N];
 condition not_full, not_empty;
 procedure add_entry(resource x) {
  while(array "resources" is full)
   wait(not_full);
  add "x" to array "resources"
  signal(not_empty);
 procedure get_entry(resource *x) {
  while (array "resources" is empty)
   wait(not_empty);
  *x = get resource from array "resources"
  signal(not_full);
```

Two Kinds of Monitors

- Hoare monitors: signal(c) means
 - run waiter immediately
 - signaller blocks immediately
 - condition guaranteed to hold when waiter runs
 - but, signaller must restore monitor invariants before signalling!
- Mesa monitors: signal(c) means
 - waiter is made ready, but the signaller continues
 - waiter runs when signaller leaves monitor (or waits)
 - condition is not necessarily true when waiter runs again
 - signaller need not restore invariant until it leaves the monitor
 - being woken up is only a hint that something has changed
 - must recheck conditional case

Examples

- Hoare monitors
 - if (notReady)
 - wait(c)
- Mesa monitors
 - while(notReady)
 - wait(c)
- Mesa monitors easier to use
 - more efficient
 - fewer switches
 - directly supports broadcast
- Hoare monitors leave less to chance
 - when wake up, condition guaranteed to be what you expect

Condition Variables and Mutex

- Yet another construct:
 - condition variables can be used with mutexes

```
pthread_mutex_t mu;
pthread_cond_t co;
boolean ready;
void foo( ) {
  pthread_mutex_lock(&mu);
  whiled (!ready)
    pthread_cond_wait(&co, &mu);
  ...
  ready = TRUE;
  pthread_cond_signal(&co); // unlock and signal atomically
  pthread_mutex_unlock(&mu);
}
```

- Think of a monitor as a language feature
 - under the covers, compiler knows about monitors
 - compiler inserts a mutex to control entry and exit of processes to the monitor's procedures
