

CSE 451: Operating Systems

Winter 2009

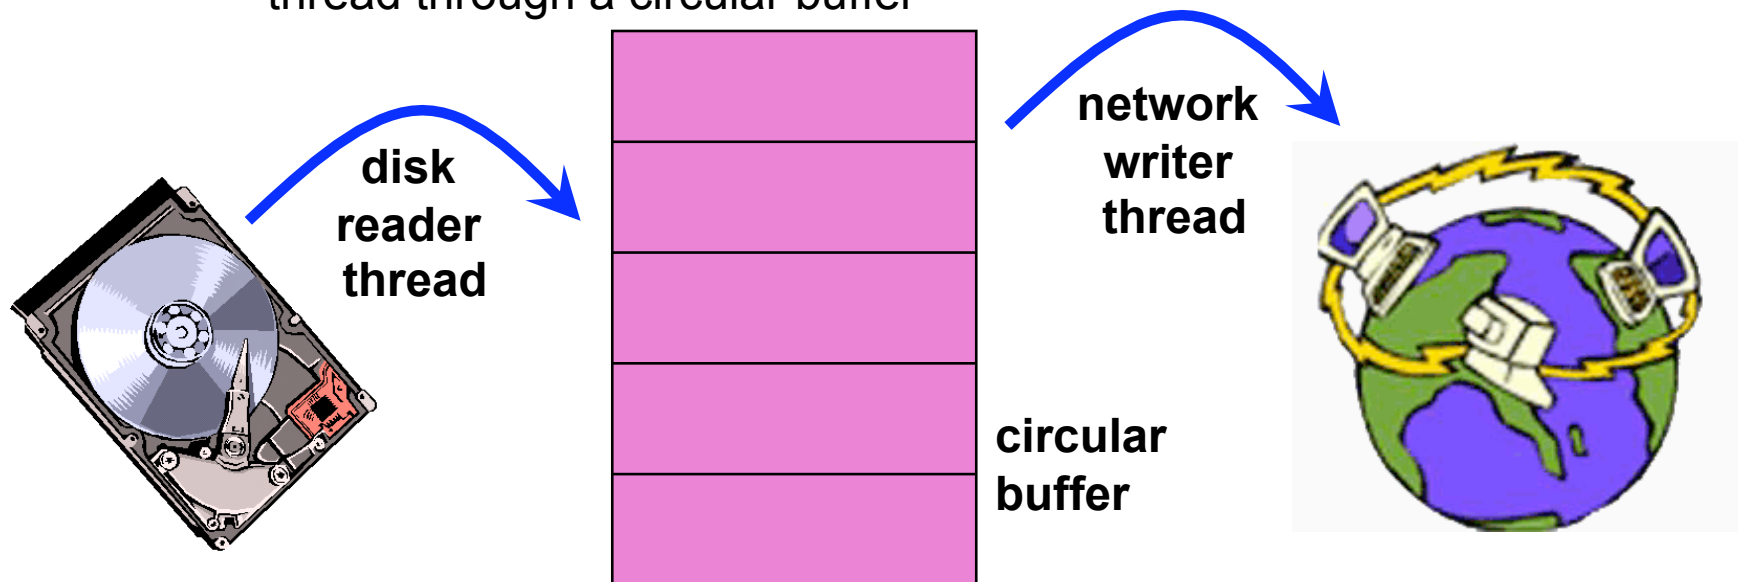

Module 7

Synchronization

Mark Zbikowski
Gary Kimura

Synchronization

- Threads cooperate in multithreaded programs
 - to **share** resources, access shared data structures
 - e.g., threads accessing a memory cache in a web server
 - also, to **coordinate** their execution
 - e.g., a disk reader thread hands off blocks to a network writer thread through a circular buffer

Synchronization

- For correctness, we have to control this cooperation
 - must assume threads **interleave executions arbitrarily** and at **different rates**
 - Modern OS's are preemptive
 - Most new machines are multicore
 - scheduling is not under application writers' control (except for real-time, but that's not of interest here).
- We control cooperation using **synchronization**
 - enables us to restrict the interleaving of executions
- Note: this also applies to processes, not just threads
 - (I'll almost never say "process" again!)
- It also applies across machines in a distributed system (Big Research Topic)

Shared resources

- We'll focus on coordinating access to shared resources
 - basic problem:
 - two concurrent threads are accessing a shared variable
 - if the variable is read/modified/written by both threads, then access to the variable must be controlled
 - otherwise, unexpected results may occur
- Over the next several lectures, we'll look at:
 - mechanisms to control access to shared resources
 - low level mechanisms like locks
 - higher level mechanisms like mutexes, semaphores, monitors, and condition variables
 - patterns for coordinating access to shared resources
 - bounded buffer, producer-consumer, ...

The classic example

- Suppose we have to implement a function to withdraw money from a bank account:

```
int withdraw(account, amount) {  
    int balance = get_balance(account);  
    balance -= amount;  
    put_balance(account, balance);  
    return balance;  
}
```

- Now suppose that you and your S.O. share a bank account with a balance of \$100.00
 - what happens if you both go to separate ATM machines, and simultaneously withdraw \$10.00 from the account?

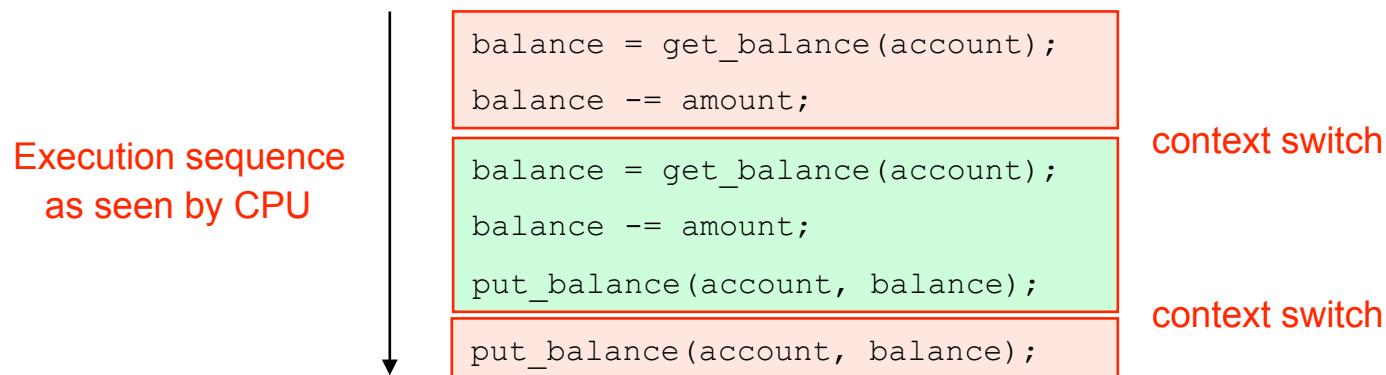

- Represent the situation by creating a separate thread for each person to do the withdrawals
 - have both threads run on the same bank mainframe:

```
int withdraw(account, amount) {  
    int balance = get_balance(account);  
    balance -= amount;  
    put_balance(account, balance);  
    return balance;  
}
```

```
int withdraw(account, amount) {  
    int balance = get_balance(account);  
    balance -= amount;  
    put_balance(account, balance);  
    return balance;  
}
```

Interleaved schedules

- The problem is that the execution of the two threads can be interleaved, assuming preemptive scheduling:

- What's the account balance after this sequence?
 - who's happy, the bank or you?
- How often is this unfortunate sequence likely to occur?

Other Execution Orders

- Which interleavings are ok? Which are not?

```
int withdraw(account, amount) {  
    int balance = get_balance(account);  
    balance -= amount;  
    put_balance(account, balance);  
    return balance;  
}
```

```
int withdraw(account, amount) {  
    int balance = get_balance(account);  
    balance -= amount;  
    put_balance(account, balance);  
    return balance;  
}
```

How About Now?

```
int xfer(from, to, amt) {  
    int bal = withdraw(from, amt);  
    deposit( to, amt );  
    return bal;  
}
```

```
int xfer(from, to, amt) {  
    int bal = withdraw(from, amt);  
    deposit( to, amt );  
    return bal;  
}
```

And This?

```
i++;
```

```
i++;
```

The crux of the matter

- The problem is that two concurrent threads (or processes) access a **shared resource** (account) without any **synchronization**
 - creates a **race condition**
 - output is non-deterministic, depends on timing
- We need mechanisms for controlling access to shared resources in the face of concurrency
 - so we can reason about the operation of programs
 - essentially, **re-introducing determinism**
- Synchronization is necessary for any shared data structure
 - buffers, queues, lists, hash tables, scalars, ...

What resources are shared?

- Local variables are *not* shared
 - refer to data on the stack, each thread has its own stack
 - *never pass/share/store a pointer to a local variable on another thread's stack!*
- Global variables are shared
 - stored in the static data segment, accessible by any thread
- Dynamic objects are shared
 - stored in the heap, shared if you can name it
 - in C, can conjure up the pointer
 - e.g., `void *x = (void *) 0xDEADBEEF`
 - in Java/C#, strong typing prevents this
 - must pass references explicitly

Mutual exclusion

- We want to use **mutual exclusion** to synchronize access to shared resources
- Mutual exclusion makes reasoning about program behavior easier
 - making reasoning easier leads to fewer bugs
- Code that uses mutual exclusion to synchronize its execution is called a **critical section**
 - only one thread at a time can execute in the critical section
 - all other threads are forced to wait on entry
 - when a thread leaves a critical section, another can enter

Critical section requirements

- Critical sections have the following requirements
 - mutual exclusion
 - at most one thread is in the critical section
 - progress
 - if thread T is outside the critical section, then T cannot prevent thread S from entering the critical section
 - bounded waiting (no starvation)
 - if thread T is waiting on the critical section, then T will eventually enter the critical section
 - assumes threads eventually leave critical sections
 - vs. fairness?
 - performance
 - the overhead of entering and exiting the critical section is small with respect to the work being done within it

Mechanisms for building critical sections

- Locks
 - very primitive, minimal semantics; used to build others
- Semaphores
 - basic, easy to get the hang of, hard to program with
- Monitors
 - high level, requires language support, implicit operations
 - easy to program with; Java “`synchronized()`” as an example
- Messages
 - simple model of communication and synchronization based on (atomic) transfer of data across a channel
 - direct application to distributed systems (SOAP, RPC)

Locks

- A lock is a object (in memory) that provides the following two operations:
 - `acquire()`: a thread calls this before entering a critical section
 - `release()`: a thread calls this after leaving a critical section
- Threads pair up calls to `acquire()` and `release()`
 - between `acquire()` and `release()`, the thread **holds** the lock
 - `acquire()` does not return until the caller holds the lock
 - at most one thread can hold a lock at a time (usually)
 - so: what can happen if the calls aren't paired?
- Two basic flavors of locks
 - spinlock
 - blocking (a.k.a. “mutex”)

Using locks

```
int withdraw(account, amount) {  
    acquire(lock);  
    balance = get_balance(account);  
    balance -= amount;  
    put_balance(account, balance);  
    release(lock);  
    return balance;  
}
```

} critical section

acquire(lock)
balance = get_balance(account);
balance -= amount;

acquire(lock)

put_balance(account, balance);
release(lock);

balance = get_balance(account);
balance -= amount;
put_balance(account, balance);
release(lock);

- What happens when green tries to acquire the lock?
- Why is the “return” outside the critical section?
 - is this ok?

Spinlocks

- How do we implement locks? Here's one attempt:

```
struct lock {  
    int held = 0;  
}  
void acquire(lock) {  
    while (lock->held);  
    lock->held = 1;  
}  
void release(lock) {  
    lock->held = 0;  
}
```

the caller "busy-waits",
or spins, for lock to be
released \Rightarrow hence spinlock

- Why doesn't this work?
 - where is the race condition?

Implementing locks (cont.)

- Problem is that implementation of locks has critical sections, too!
 - the acquire/release must be **atomic**
 - atomic == executes as though it could not be interrupted
 - code that executes “all or nothing”
- Need help from the hardware
 - disable/enable interrupts
 - to prevent context switches
 - atomic instructions
 - test-and-set, compare-and-swap, ...
 - multiple processors?

Spinlocks redux: Test-and-Set

- CPU provides the following as **one atomic instruction**:

```
bool test_and_set(bool *flag) {  
    bool old = *flag;  
    *flag = True;  
    return old;  
}
```

- Remember, this is a single instruction...

Spinlocks redux: Test-and-Set

- So, to fix our broken spinlocks, do:

```
struct lock {  
    int held = 0;  
}  
  
void acquire(lock) {  
    while(test_and_set(&lock->held));  
}  
  
void release(lock) {  
    lock->held = 0;  
}
```

- mutual exclusion?
- progress?
- bounded waiting?
- performance?

Real World Example

- Windows XP AcquireSpinlock

```
AcquireSpinlock:
;
; Attempt to assert the lock
;
    lock bts dword ptr [LockAddress], 0
    jc    SpinLabel ; spinlock owned
    ret
SpinLabel:
;
; Was spinlock cleared?
;
    test  dword ptr [LockAddress], 1
    jz    AcquireSpinlock
    YIELD
    jmp   Spinlabel
;
; ...
```

Reminder of use ...

```
int withdraw(account, amount) {  
    acquire(lock);  
    balance = get_balance(account);  
    balance -= amount;  
    put_balance(account, balance);  
    release(lock);  
    return balance;  
}
```

} critical section

```
acquire(lock)  
balance = get_balance(account);  
balance -= amount;
```

```
acquire(lock)
```

```
put_balance(account, balance);  
release(lock);
```

```
balance = get_balance(account);  
balance -= amount;  
put_balance(account, balance);  
release(lock);
```

- How does a thread blocked on an “acquire” (that is, stuck in a test-and-set loop) yield the CPU?
 - calls `yield()` (*spin-then-block*)
 - there’s an involuntary context switch

Problems with spinlocks

- Spinlocks work, but are horribly wasteful!
 - if a thread is spinning on a lock, the thread holding the lock cannot make progress
 - And neither can anyone else! Why?
- Only want spinlocks as primitives to build higher-level synchronization constructs
 - Why is this okay?
- *When might the above points be misleading?*

Another approach: Disabling interrupts

```
struct lock {  
}  
void acquire(lock) {  
    cli();    // disable interrupts  
}  
void release(lock) {  
    sti();    // reenable interrupts  
}
```

Problems with disabling interrupts

- Only available to the kernel
 - Can't allow user-level to disable interrupts!
- Insufficient on a multiprocessor
 - Each processor has its own interrupt mechanism
- “Long” periods with interrupts disabled can wreak havoc with devices
- Just as with spinlocks, you only want to use disabling of interrupts to build higher-level synchronization constructs

Summary

- Synchronization can be provided by locks, semaphores, monitors, messages ...
- Locks are the lowest-level mechanism
 - very primitive in terms of semantics – error-prone
 - implemented by spin-waiting (crude) or by disabling interrupts (also crude, and can only be done in the kernel)
- In our next exciting episode ...
 - semaphores are a slightly higher level abstraction
 - less crude implementation too
 - monitors are significantly higher level
 - utilize programming language support to reduce errors
