Concurrency
Motivation

• Operating systems (and application programs) often need to be able to handle multiple things happening at the same time
  – Process execution, interrupts, background tasks, system maintenance
• Humans are not very good at keeping track of multiple things happening simultaneously
• Threads are an abstraction to help bridge this gap
Why Concurrency?

• Servers
  – Multiple connections handled simultaneously
• Parallel programs
  – To achieve better performance
• Programs with user interfaces
  – To achieve user responsiveness while doing computation
• Network and disk bound programs
  – To hide network/disk latency
Déjà vu?

• Didn’t we learn all about concurrency in CSE 332/333?
  – More practice
    • Realistic examples, especially in the project
  – Design patterns and pitfalls
    • Methodology for writing correct concurrent code
  – Implementation
    • How do threads work at the machine level?
  – CPU scheduling
    • If multiple threads to run, which do we do first?
Definitions

• A thread is a single execution sequence that represents a separately schedulable task
  – Single execution sequence: familiar programming model
  – Separately schedulable: OS can run or suspend a thread at any time

• Protection is an orthogonal concept
  – Can have one or many threads per protection domain
Threads in the Kernel and at User-Level

- **Multi-threaded kernel**
  - multiple threads, sharing kernel data structures, capable of using privileged instructions
  - OS/161 assignment 1

- **Multiprocess kernel**
  - Multiple single-threaded processes
  - System calls access shared kernel data structures
  - OS/161 assignment 2

- **Multi-threaded user program**
  - multiple threads, sharing same data structures, isolated from other user programs

- **Multiple multi-threaded processes**
Thread Abstraction

- Infinite number of processors
- Threads execute with variable speed
  - Programs must be designed to work with any schedule
### Programmer vs. Processor View

Possible Executions

One Execution

Thread 1
Thread 2
Thread 3

Another Execution

Thread 1
Thread 2
Thread 3

Another Execution

Thread 1
Thread 2
Thread 3
Thread Operations

- thread_create(thread, func, args)
  - Create a new thread to run func(args)
  - OS/161: thread_fork

- thread_yield()
  - Relinquish processor voluntarily
  - OS/161: thread_yield

- thread_join(thread)
  - In parent, wait for forked thread to exit, then return
  - OS/161: assignment 1

- thread_exit
  - Quit thread and clean up, wake up joiner if any
  - OS/161: thread_exit
Example: threadHello

```c
#define NTHREADS 10
thread_t threads[NTHREADS];
main() {
    for (i = 0; i < NTHREADS; i++)
        thread_create(&threads[i], &go, i);
    for (i = 0; i < NTHREADS; i++)
        exitValue = thread_join(threads[i]);
    printf("Thread %d returned with %ld\n", i, exitValue);
}
printf("Main thread done.\n");
}
void go (int n) {
    printf("Hello from thread %d\n", n);
    thread_exit(100 + n);
    // REACHED?
}
```
threadHello: Example Output

- Why must “thread returned” print in order?
- What is maximum # of threads running when thread 5 prints hello?
- Minimum?

bash-3.2$ ./threadHello
Hello from thread 0
Hello from thread 1
Thread 0 returned 100
Hello from thread 3
Hello from thread 4
Thread 1 returned 101
Hello from thread 5
Hello from thread 2
Hello from thread 6
Hello from thread 8
Hello from thread 7
Hello from thread 9
Thread 2 returned 102
Thread 3 returned 103
Thread 4 returned 104
Thread 5 returned 105
Thread 6 returned 106
Thread 7 returned 107
Thread 8 returned 108
Thread 9 returned 109
Main thread done.
Fork/Join Concurrency

- Threads can create children, and wait for their completion
- Data only shared before fork/after join
- Examples:
  - Web server: fork a new thread for every new connection
    - As long as the threads are completely independent
  - Merge sort
  - Parallel memory copy
bzero with fork/join concurrency

void blockzero (unsigned char *p, int length) {
    int i, j;
    thread_t threads[NTHREADS];
    struct bzeroparams params[NTHREADS];

    // For simplicity, assumes length is divisible by NTHREADS.
    for (i = 0, j = 0; i < NTHREADS; i++, j += length/NTHREADS) {
        params[i].buffer = p + i * length/NTHREADS;
        params[i].length = length/NTHREADS;
        thread_create_p(&(threads[i]), &go, &params[i]);
    }
    for (i = 0; i < NTHREADS; i++) {
        thread_join(threads[i]);
    }
}
Thread Data Structures

Shared State

- Code
- Global Variables
- Heap

Thread 1’s
Per–Thread State

- Thread Control Block (TCB)
  - Stack Information
  - Saved Registers
  - Thread Metadata

Thread 2’s
Per–Thread State

- Thread Control Block (TCB)
  - Stack Information
  - Saved Registers
  - Thread Metadata
Thread Lifecycle

- Thread Creation: sthread_create()
- Scheduler Resumes Thread
- Thread Exit: sthread_exit()
- Thread Yield/Scheduler Suspends Thread: sthread_yield()
- Event Occurs: Other Thread Calls sthread_join()
- Waiting
- Thread Waits for Event: sthread_join()
Implementing Threads: Roadmap

• Kernel threads
  – Thread abstraction only available to kernel
  – To the kernel, a kernel thread and a single threaded user process look quite similar

• Multithreaded processes using kernel threads (Linux, MacOS)
  – Kernel thread operations available via syscall

• User-level threads
  – Thread operations without system calls
Multithreaded OS Kernel

Kernel

- Code
- Globals
- Stack
- Heap
- TCB 1
- TCB 2
- TCB 3
- PCB 1
- PCB 2

User-Level Processes

- Process 1
  - Thread
  - Stack
  - Code
  - Globals
  - Heap
- Process 2
  - Thread
  - Stack
  - Code
  - Globals
  - Heap
Implementing threads

• Thread_fork(func, args)
  – Allocate thread control block
  – Allocate stack
  – Build stack frame for base of stack (stub)
  – Put func, args on stack
  – Put thread on ready list
  – Will run sometime later (maybe right away!)

• stub(func, args): OS/161 mips_threadstart
  – Call (*func)(args)
  – If return, call thread_exit()
Thread Stack

• What if a thread puts too many procedures on its stack?
  – What happens in Java?
  – What happens in the Linux kernel?
  – What happens in OS/161?
  – What *should* happen?
Thread Context Switch

• Voluntary
  – Thread_yield
  – Thread_join (if child is not done yet)

• Involuntary
  – Interrupt or exception
  – Some other thread is higher priority
Voluntary thread context switch

- Save registers on old stack
- Switch to new stack, new thread
- Restore registers from new stack
- Return
- Exactly the same with kernel threads or user threads
  - OS/161: thread switch is always between kernel threads, not between user process and kernel thread
/* a0: old thread stack pointer
 * a1: new thread stack pointer */

/* Allocate stack space for 10 registers. */
addi sp, sp, -40

/* Save the registers */

addi sp, sp, 40 /* in delay slot */
x86 switch_threads (oldT, nextT)

# Save caller’s register state
# NOTE: %eax, etc. are ephemeral
pushl %ebx
pushl %ebp
pushl %esi
pushl %edi

# Get offsetof (struct thread, stack)
mov thread_stack_stack_offs, %edx
# Save current stack pointer to old
thread's stack, if any.
movl SWITCH_CUR(%esp), %eax
movl %esp, (%eax,%edx,1)

# Change stack pointer to new
thread's stack
# this also changes currentThread
movl SWITCH_NEXT(%esp), %ecx
movl (%ecx,%edx,1), %esp

# Restore caller's register state.
popl %edi
papl %esi
papl %ebp
papl %ebx
ret
A Subtlety

• Thread_create puts new thread on ready list
• When it first runs, some thread calls switchframe
  – Saves old thread state to stack
  – Restores new thread state from stack
• Set up new thread’s stack as if it had saved its state in switchframe
  – “returns” to stub at base of stack to run func
Two Threads Call Yield

Thread 1’s instructions
“return” from thread_switch into stub
call go
call thread_yield
choose another thread
call thread_switch
save thread 1 state to TCB
load thread 2 state

Thread 2’s instructions
“return” from thread_switch into stub
call go
call thread_yield
choose another thread
call thread_switch
save thread 2 state to TCB
load thread 1 state

Processor’s instructions
“return” from thread_switch into stub
call go
call thread_yield
choose another thread
call thread_switch
save thread 1 state to TCB
load thread 2 state
“return” from thread_switch into stub
call go
call thread_yield
choose another thread
call thread_switch
save thread 2 state to TCB
load thread 1 state

return from thread_switch
return from thread_yield
call thread_yield
choose another thread
call thread_switch

return from thread_switch
return from thread_yield
call thread_yield
choose another thread
call thread_switch

...
Involuntary Thread Switch

- Timer or I/O interrupt
  - Tells OS some other thread should run
- Simple version (OS/161)
  - End of interrupt handler calls schedule()
  - When resumed, return from handler resumes
    kernel thread or user process
- Faster version (Linux)
  - Interrupt handler returns to saved state in TCB
  - Could be kernel thread or user process
Multithreaded User Processes (Take 1)

- User thread = kernel thread (Linux, MacOS)
  - System calls for thread fork, join, exit (and lock, unlock, ...)
  - Kernel does context switch
  - Simple, but a lot of transitions between user and kernel mode
Multithreaded User Processes (Take 1)
Multithreaded User Processes (Take 2)

• Green threads (early Java)
  – User-level library, within a single-threaded process
  – Library does thread context switch
  – Preemption via upcall/UNIX signal on timer interrupt
  – Use multiple processes for parallelism
    • Shared memory region mapped into each process
Multithreaded User Processes (Take 3)

• Scheduler activations (Windows 8)
  – Kernel allocates processors to user-level library
  – Thread library implements context switch
  – Thread library decides what thread to run next

• Upcall whenever kernel action requires (user-level) scheduling decision
  • Process assigned a new processor
  • Processor removed from process
  • System call blocks in kernel
Question

• Compare event-driven programming with multithreaded concurrency. Which is better in which circumstances, and why?
