Section 7: Intro to Lab 4

CSE 451 19sp
Memory vs Disk

- **Memory is in close proximity to the CPU**
  - Fast!
  - Volatile (loss of power == loss of all data in memory)
  - More expensive

- **Disk is farther away from the CPU**
  - Much slower than main memory
  - Non-volatile (loss of power != loss of data), persistent
  - Less expensive

Diagram from CSE 351 18WI slides
Virtual Memory

- Illusion that each process has all of memory to itself
- Would be nice if this illusion held even when processes together use more space than available in memory

Memory

```
[Page 1]
Process 1
Using 512 pages

[Page 2]
Process 2
Using 256 pages

[Page 3]
Process 3
Using 256 pages

[Page 4]

[Page 5]

[Page 6]

[Page 7]

[Page 9]

[Page 10]

[Page 11]

[Page 12]

[Page 13]

[Page 1024]

Pages Used

512

768

1024

1280!
```

After lab 4, this will be possible!
Creating the illusion of more memory

- Since we need to make it seem like there is more than 4MB of memory, we will need somewhere else to store data.
- Can use the disk to store extra data, and page it in to memory on demand (called “paging”).
Paging Example - Assumes OS has only 4 pages memory for simplicity

This mapping could be obtained as a result of the following requests:

Proc 1: Requests a page of memory
Proc 2: Requests a page of memory
Proc 1: Requests a page of memory
Proc 2: Requests a page of memory

Note: This example is highly simplified
Paging Example - Swap page to disk

1. Move the least recently used page to disk!
2. Allocate the new page!
Process 1 tries to read from its 1st page.

Page Fault!

Need to make room for the page stored on disk.

1. Move the least recently used page to disk to make room!
Process 1 tries to read from its 1st page. Page Fault! Now that we have an empty spot in memory:

2. Move the requested page into memory.

= Available  = In Use
XK’s hardware is emulated by QEMU. In `kernel/Makefrag` we set up the options we will pass to QEMU.

Before (Labs 1 - 3):

16MB (4096 pages)

After (Lab 4):

4MB (1024 pages)

QEMUOPTS += -m 16M

QEMUOPTS += -m 4M
XK’s Disk

- Set up in **mkfs.c** (this file is used by QEMU, run by the host OS before XK boots and sets up the disk)
- Need to add a swap region to use for pages swapped out to disk

<table>
<thead>
<tr>
<th>Boot Block</th>
<th>Super Block</th>
<th>Bitmap</th>
<th>Inodes</th>
<th>Extent</th>
<th>Unused</th>
</tr>
</thead>
</table>

- 512 bytes in a disk block
- 4096 bytes in a page
- Therefore, need 8 disk blocks per swap page

Add Swap Region Here!
Representing the Swap

- How do you add the swap region to disk?
  - Hint: lab4.md diagram and mkfs.c

- How should we keep track of a memory page that is in swap region?
  - Hint: See how kalloc.c tracks physical pages for a design example

- How do you track in a vspace whether a page is in physical memory or swap memory?
  - Hint: look at vpage_info and how that was used in Lab 3 COW fork

- What should happen when a swapped memory page is shared via copy-on-write fork?
Swap In

- When should we load pages from the swap region?
  - Hint: similar to lab 3’s “when should we make a physical copy of a COW page?”

- When a page is swapped in, what needs to be updated?
  - Hint: who/what keeps track of whether a virtual page is in the swap?
Swap Out

- When should we flush pages to the swap?
  - Hint: Look at `kalloc.c` and at the algorithm in `lab4.md`

- Is there a set of memory pages you don't want to flush to swap?
  - Hint: What happens if the trap code page is in the swap?

- When a page is swapped out, what needs to be updated?
  - Hint: who/what keeps track of whether a virtual page is present in physical memory?
