Memcache as a Service

Tom Anderson

Goals

Rapid application development
- Speed of adding new features is paramount
Scale
- Billions of users
- Every user on FB all the time
Performance
- Low latency for every user everywhere
Fault tolerance
- Scale implies failures
Consistency model:
- “Best effort eventual consistency”

Facebook’s Scaling Problem

• Rapidly increasing user base
  - Small initial user base
  - 2x every 9 months
  - 2013: 1B users globally
• Users read/update many times per day
  - Increasingly intensive app logic per user
  - 2x I/O every 4-6 months
• Infrastructure has to keep pace

Scaling Strategy

Adapt off the shelf components where possible
Fix as you go
- no overarching plan
Rule of thumb: Every order of magnitude requires a rethink

Facebook Three Layer Architecture

• Application front end
  - Stateless, rapidly changing program logic
  - If app server fails, redirect client to new app server
• Memcache
  - Lookaside key-value cache
  - Keys defined by app logic (can be computed results)
• Fault tolerant storage backend
  - Stateful
  - Careful engineering to provide safety and performance
  - Both SQL and NoSQL

Workload

Each user’s page is unique
- draws on events posted by other users
Users not in cliques
- For the most part
User popularity is zipf
- Some user posts affect very large #’s of other pages
- Most affect a much smaller number
Workload

• Many small lookups
• Many dependencies
• App logic: many diffuse, chained reads
  – latency of each read is crucial
• Much smaller update rate
  – still large in absolute terms

Scaling

• A few servers
• Many servers
• An entire data center
• Many data centers

Each step 10-100x previous one

Facebook

• Scale by hashing to partitioned servers
• Scale by caching
• Scale by replicating popular keys
• Scale by replicating clusters
• Scale by replicating data centers

Scale By Consistent Hashing

Hash users to front end web servers
Hash keys to memcache servers
Hash files to SQL servers

Result of consistent hashing is all to all communication pattern
  – Each web server pulls data from all memcache servers and all storage servers

Scale By Caching: Memcache

Sharded in-memory key-value cache
  – Key, values assigned by application code
  – Values can be data, result of computation
  – Independent of backend storage architecture (SQL, noSQL) or format
  – Design for high volume, low latency

Lookaside Read

Web Server
  get k (1)

Cache
  data

SQL
Lookaside Read

Web Server

get k (1) → Cache

get k (2) → data nope!

SQL

Put k (3) → Cache

get k (2) → data ok!

SQL

Lookaside Operation (Read)

• Webserver needs key value
• Webserver requests from memcache
• Memcache: If in cache, return it
• If not in cache:
  – Return error
  – Webserver gets data from storage server
  – Possibly an SQL query or complex computation
  – Webserver stores result back into memcache

Question

What if swarm of users read same key at the same time?

Lookaside Write

Web Server

update (1) → Cache

delete k (2) → ok! ok!

SQL

Lookaside Operation (Write)

• Webserver changes a value that would invalidate a memcache entry
  – Could be an update to a key
  – Could be an update to a table
  – Could be an update to a value used to derive some key value
• Client puts new data on storage server
• Client invalidates entry in memcache
**Why Not Delete then Update?**

1. **Web Server**
   - Update (2)
   - Delete k (1)
   - Cache
   - Cache
   - SQL
   - SQL
   - OK!
   - OK!

**Memcache Consistency**

Is memcache linearizable?

**Example**

- **Webserver: Reader**
  - Read cache
  - If missing,
    - Fetch from database
    - Store back to cache
- **Webserver: Writer**
  - Change database
  - Delete cache entry

Interleave any # of readers/writers

**Example**

- **Webserver: Reader**
  - Read cache
- **Webserver: Writer**
  - Change database
  - Delete cache entry

What if we delete cache entry, then change database?
Memcache Consistency

Is the lookaside protocol eventually consistent?

Example

- Read cache
- Read database
  - change database
  - Delete entry
- Store back to cache

Lookaside With Leases

Goals:
- Reduce (eliminate?) per-key inconsistencies
- Reduce cache miss swarms

On a read miss:
- leave a marker in the cache (fetch in progress)
- return timestamp
- check timestamp when filling the cache
- if changed means value has (likely) changed: don’t overwrite

If another thread read misses:
- find marker and wait for update (retry later)

Question

What if web server crashes while holding lease?

Question

Is lookaside with leases linearizable?

Example

Webserver: Reader
- Change database
  - Read cache
- Delete cache entry
Question

Is lookaside with leases eventually consistent?

Example

Webserver: Reader
Read cache
Webserver: Writer
Change database
Read cache
CRASH!
(before Delete cache entry)

Question

Would this be linearizable?
- read misses obtain lease
- writes obtain lease (prevent reads during update)

Except that
- FB replicates popular keys (need lease on every copy?)
- memcache server might fail, or appear to fail by being slow (e.g., to some nodes, but not others)

Latency Optimizations

Concurrent lookups
- Issue many lookups concurrently
- Prioritize those that have chained dependencies

Batching
- Batch multiple requests (e.g., for different end users) to the same memcache server

Incast control:
- Limit concurrency to avoid collisions among RPC responses

More Optimizations

Return stale data to web server if lease is held
- No guarantee that concurrent requests returning stale data will be consistent with each other

Partitioned memory pools
- Infrequently accessed, expensive to recompute
- Frequently accessed, cheap to recompute
- If mixed, frequent accesses will evict all others

Replicate keys if access rate is too high
- Implication for consistency?

Gutter Cache

When a memcache server fails, flood of requests to fetch data from storage layer
- Slows users needing any key on failed server
- Slows other users due to storage server contention

Solution: backup (gutter) cache
- Time-to-live invalidation (ok if clients disagree as to whether memcache server is still alive)
- TTL is eventually consistent
Scaling Within a Cluster

What happens as we increase the number of memcache servers to handle more load?

- Recall: All to all communication pattern
- Less data between any pair of nodes: less batching
- Need even more replication of popular keys
- More failures: need bigger gutter cache
- ...

Multi-Cluster Scaling

Multiple independent clusters within data center

- Each with front-ends, memcache servers
- Data replicated in the caches in each partition
- Shared storage backend

Data is replicated in each cluster (inefficient?)

- need to invalidate every cluster on every update

Instead:

- invalidate local cluster on update (read my writes)
- background invalidate driven off of database update log
- temporary inconsistency!

Multi-Cluster Scaling

Web server driven invalidation?

- need to invalidate every cluster on every update

Instead: mcsqueal

- invalidate local cluster on update (read my writes)
- background invalidate driven off of database update log
- temporary inconsistency!

mcsqueal

Web servers talk to local memcache. On update:

- Acquire local lease
- Tell storage layer which keys to invalidate
- Invalidate local memcache

Storage layer sends invalidations to other clusters

- Scan database log for updates/invalidations
- Batch invalidations to each cluster (mcrouter)
- Forward/batch invalidations to remote memcache servers

Per-Cluster vs. Multi-Cluster

Per-cluster memcache servers

- Frequently accessed data
- Inexpensive to compute data
- Lower latency, less efficient use of memory

Shared multi-cluster memcache servers

- infrequently accessed
- hard to compute data
- higher latency, more memory efficient

Cold Start Consistency

During new cluster startup:

- Many cache misses!
- Lots of extra load on SQL servers

Instead of going to SQL server on cache miss:

- Webserver gets data from warm memcache cluster
- Puts data into local cluster
- Subsequent requests hit in local cluster
**Example: Local Update**

- B: change database
- B: queue remote invalidation
- B: Delete local mc entry

**A:**
- Local cache miss
- Read remote cluster
- Put data in local cache

**Apply remote invalidation**

**Solution:** prevent local cache fills within 2 seconds of delete

---

**Multi-Region Scaling**

**Storage layer consistency**
- Storage at one data center designated as primary
- All updates applied at primary
- Updates propagated in background to other data centers
- Invalidations to memcache layer delayed until after update reaches that site

**However**
- Webservers may read stale data
- Even data that they just wrote

---

**Multi-Region Consistency**

To perform an update to key:
- Put marker into local region
- Send write to primary region
- Delete local copy

On a cache miss:
- Check if local marker
- If so, fetch data from primary region
- Fill local copy

---

**Data Centers without Data**

**Tradeoff in increasing number of data centers**
- Lower latency when data near clients
- More consistency overhead
- More opportunity for inconsistency

**Mini-data centers**
- Front end web servers
- Memcache servers
- No backend storage: remote access for cache misses
