Image filtering

Images by Pawan Sinha

Reading

Forsyth & Ponce, chapters 8.1-8.2

What is an image?

We can think of an **image** as a function, *f*, from R^2 to R:

- *f*(*x, y*) gives the **intensity** at position (*x, y*)
- Realistically, we expect the image only to be defined over a rectangle, with a finite range:
  - *f*: [*a,b*]x[*c,d*] $\rightarrow$ [0,1]

A color image is just three functions pasted together. We can write this as a "vector-valued" function:

$$f(x,y) = \begin{bmatrix} r(x,y) \\ g(x,y) \\ b(x,y) \end{bmatrix}$$

Images as functions

What is a digital image?

In computer vision we usually operate on **digital** (**discrete**) images:

- **Sample** the 2D space on a regular grid
- **Quantize** each sample (round to nearest integer)

If our samples are Δ apart, we can write this as:

$f[i, j]$ = Quantize{ $f(i\,\Delta, j\,\Delta)$ }

The image can now be represented as a matrix of integer values

166	63	127	17	1	0	99	30

Image processing

An **image processing** operation typically defines a new image g in terms of an existing image f.

We can transform either the domain or the range of f.

Range transformation:

$$g(x, y) = t(f(x, y))$$

What's kinds of operations can this perform?

Image processing

Some operations preserve the range but change the domain of f:

$$g(x, y) = f(t_x(x, y), t_y(x, y))$$

What kinds of operations can this perform?

Noise

Image processing is useful for noise reduction...

Original   Salt and pepper noise

Impulse noise   Gaussian noise

Common types of noise:

- **Salt and pepper noise**: contains random occurrences of black and white pixels
- **Impulse noise:** contains random occurrences of white pixels
- **Gaussian noise**: variations in intensity drawn from a Gaussian normal distribution

Practical noise reduction

How can we "smooth" away noise in a single image?

Cross-correlation filtering

Let's write this down as an equation. Assume the averaging window is (2k+1)x(2k+1):

$$G[i,j] = \frac{1}{(2k+1)^2} \sum_{u=-k}^{k} \sum_{v=-k}^{k} F[i+u, j+v]$$

We can generalize this idea by allowing different weights for different neighboring pixels:

$$G[i,j] = \sum_{u=-k}^{k} \sum_{v=-k}^{k} H[u,v] F[i+u, j+v]$$

This is called a **cross-correlation** operation and written:

$$G = H \otimes F$$

H is called the "filter," "kernel," or "mask."

The above allows negative filter indices. When you implement need to use: H[u+k,v+k] instead of H[u,v]

14

Mean kernel

What's the kernel for a 3x3 mean filter?

$H[u,v]$

$F[x,y]$
15

Gaussian Filtering

A Gaussian kernel gives less weight to pixels further from the center of the window

$$\frac{1}{16} \begin{array}{|c|c|c|} \hline 1 & 2 & 1 \\ \hline 2 & 4 & 2 \\ \hline 1 & 2 & 1 \\ \hline \end{array}$$

$H[u,v]$

$F[x,y]$

This kernel is an approximation of a Gaussian function:

$$h(u,v) = \frac{1}{2\pi\sigma^2} e^{-\frac{u^2+v^2}{\sigma^2}}$$

16

Mean vs. Gaussian filtering

Convolution

A **convolution** operation is a cross-correlation where the filter is flipped both horizontally and vertically before being applied to the image:

$$G[i,j] = \sum_{u=-k}^{k} \sum_{v=-k}^{k} H[u,v]F[i-u, j-v]$$

It is written: $\quad G = H \star F$

Suppose H is a Gaussian or mean kernel. How does convolution differ from cross-correlation?
Median filters

A **Median Filter** operates over a window by selecting the median intensity in the window.

What advantage does a median filter have over a mean filter?

Is a median filter a kind of convolution?
