

### Content-based Image Retrieval (CBIR)

Searching a large database for images that *match* a query:

- What kinds of databases?
- What kinds of queries?
- What constitutes a match?
- How do we make such searches efficient?

#### **Applications**

- Art Collections
   e.g. Fine Arts Museum of San Francisco
- Medical Image Databases
   CT, MRI, Ultrasound, The Visible Human
- Scientific Databasese.g. Earth Sciences
- General Image Collections for Licensing Corbis, Getty Images
- The World Wide Web

#### What is a query?

- an image you already have
- a rough sketch you draw
- a symbolic description of what you want
   e.g. an image of a man and a woman on a beach

#### **SYSTEMS**

@ IBM Corporation

Query was: Random

# Some Systems You Can Try

Corbis Stock Photography and Pictures

http://pro.corbis.com/

- Corbis sells high-quality images for use in advertising, marketing, illustrating, etc.
- Search is entirely by keywords.
- Human indexers look at each new image and enter keywords.
- A thesaurus constructed from user queries is used.

IBM's QBIC (Query by Image Content)

http://wwwqbic.almaden.ibm.com

- The first commercial system.
- Uses or has-used color percentages, color layout, texture, shape, location, and keywords.

#### **Blobworld**

UC Berkeley's Blobworld

http://elib.cs.berkeley.edu/photos/blobworld

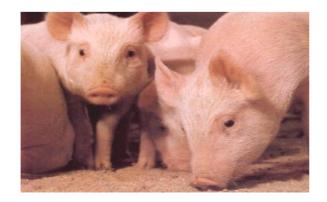

- Images are segmented on color plus texture
- User selects a region of the query image
- System returns images with similar regions
- Works really well for tigers and zebras

## **Ditto**

Ditto: See the Web

http://www.ditto.com

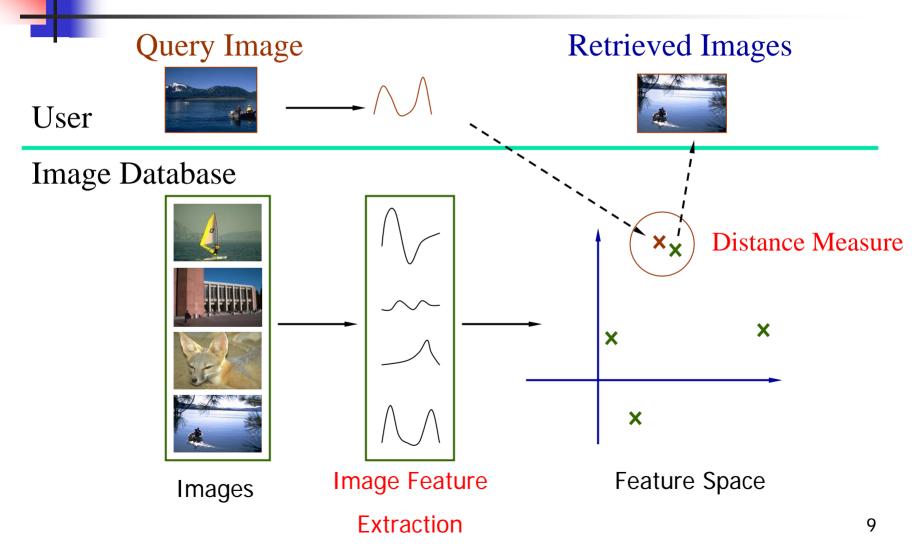

- Small company
- Allows you to search for pictures from web pages

#### Image Features / Distance Measures

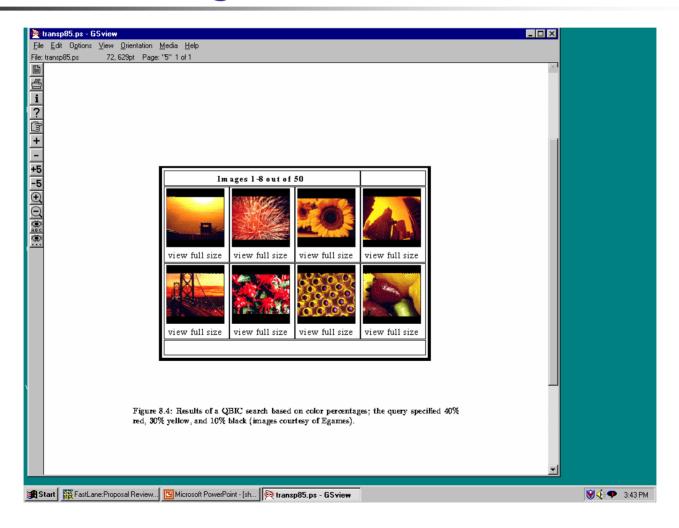

# Features

- Color (histograms, gridded layout, wavelets)
- Texture (Laws, Gabor filters, local binary pattern)
- Shape (first segment the image, then use statistical or structural shape similarity measures)
- Objects and their Relationships

This is the most powerful, but you have to be able to recognize the objects!

### **Color Histograms**

# **QBIC's Histogram Similarity**

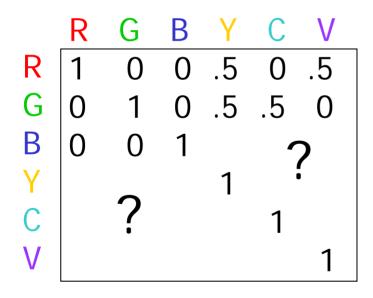

The QBIC color histogram distance is:

$$dhist(I,Q) = (h(I) - h(Q))^{T} \mathbf{A} (h(I) - h(Q))$$

- h(I) is a K-bin histogram of a database image
- h(Q) is a K-bin histogram of the query image
- A is a K x K similarity matrix

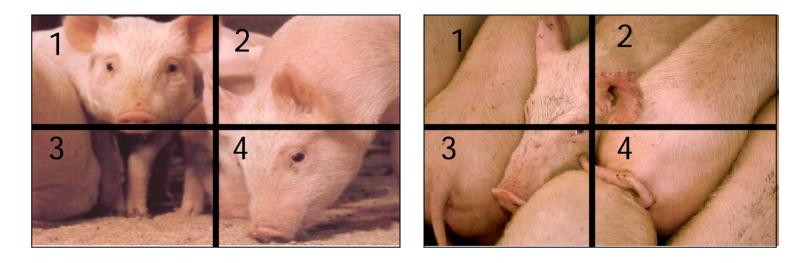

# Similarity Matrix

How similar is blue to cyan?

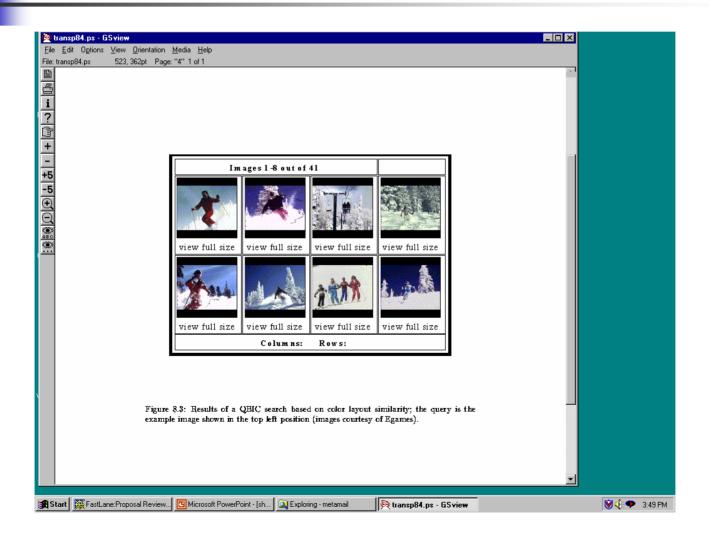

#### Gridded Color

Gridded color distance is the sum of the color distances in each of the corresponding grid squares.

What color distance would you use for a pair of grid squares?

# Color Layout (IBM's Gridded Color)

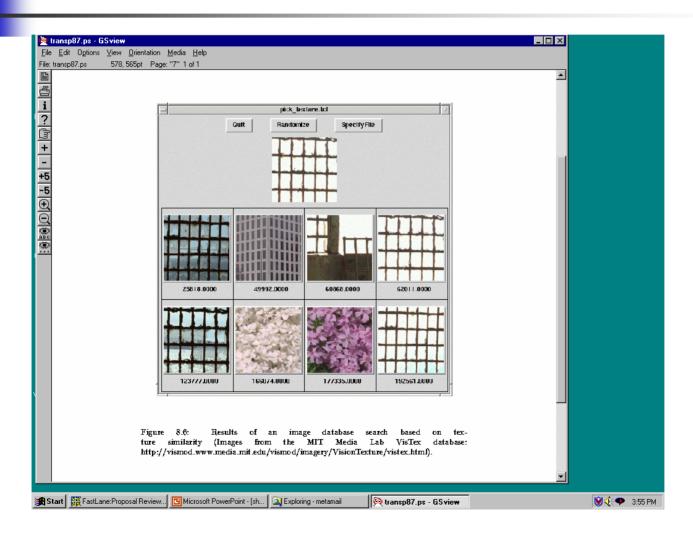

#### Texture Distances

- Pick and Click (user clicks on a pixel and system retrieves images that have in them a region with similar texture to the region surrounding it.
- Gridded (just like gridded color, but use texture).
- Histogram-based (e.g. compare the LBP histograms).

#### Laws Texture

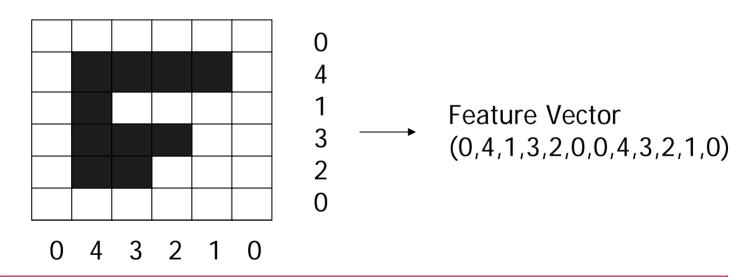

# **Shape Distances**

- Shape goes one step further than color and texture.
- It requires identification of regions to compare.
- There have been many shape similarity measures suggested for pattern recognition that can be used to construct shape distance measures.

# Global Shape Properties: Projection Matching

In projection matching, the horizontal and vertical projections form a histogram.

What are the weaknesses of this method? strengths?

# Global Shape Properties: Tangent-Angle Histograms

Is this feature invariant to starting point? Is it invariant to size, translation, rotation?

# **Boundary Matching**

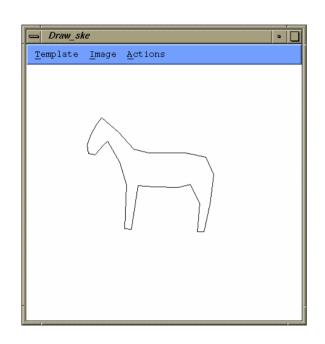

- Fourier Descriptors
- Sides and Angles
- Elastic Matching

The distance between query shape and image shape has two components:

- 1. energy required to deform the query shape into one that best matches the image shape
- 2. a measure of how well the deformed query matches the image

### Del Bimbo Elastic Shape Matching

query

retrieved images

#### Regions and Relationships

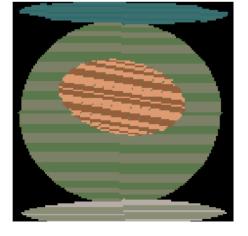

- Segment the image into regions
- Find their properties and interrelationships
- Construct a graph representation with nodes for regions and edges for spatial relationships
- Use graph matching to compare images

Like what?

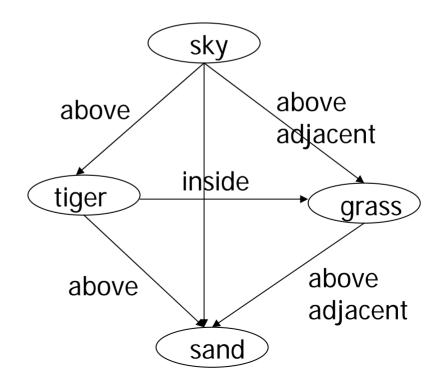

# Tiger Image as a Graph

image

abstract regions

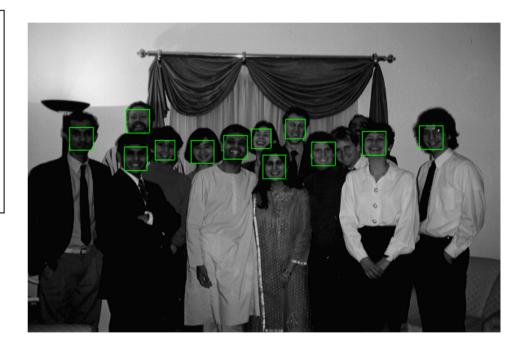

## Object Detection: Rowley's Face Finder

- 1. convert to gray scale
- 2. normalize for lighting\*
- 3. histogram equalization
- 4. apply neural net(s) trained on 16K images

What data is fed to the classifier?

32 x 32 windows in a pyramid structure

<sup>\*</sup> Like first step in Laws algorithm, p. 220

# Fleck and Forsyth's Flesh Detector

See Transparencies

The "Finding Naked People" Paper

- Convert RGB to HSI
- Use the intensity component to compute a texture map texture = med2 ( | I - med1(I) | )
- If a pixel falls into either of the following ranges, it's a potential skin pixel

```
texture < 5, 110 < hue < 150, 20 < saturation < 60 texture < 5, 130 < hue < 170, 30 < saturation < 130
```

Look for LARGE areas that satisfy this to identify pornography.

# Wavelet Approach

Idea: use a wavelet decomposition to represent images

#### What are wavelets?

- compression scheme
- uses a set of 2D basis functions
- representation is a set of coefficients, one for each basis function

# Jacobs, Finkelstein, Salesin Method for Image Retrieval (1995)

- 1. Use YIQ color space
- 2. Use Haar wavelets
- 3. 128 x 128 images yield 16,384 coefficients x 3 color channels
- 4. Truncate by keeping the 40-60 largest coefficients (make the rest 0)
- 5. Quantize to 2 values (+1 for positive, -1 for negative)

### JFS Distance Metric

$$d(I,Q) = w_{00} | Q[0,0] - I[0,0] | + \sum_{ij} w_{ij} | Q'[i,j] - I'[i,j] |$$

where the w's are weights,

Q[0,0] and I[0,0] are scaling coefficients related to average image intensity,

Q'[i,j] and I'[i,j] are the truncated, quantized coefficients.

# Experiments

20,558 image database of paintings

20 coefficients used

User "paints" a rough version of the painting he /she wants on the screen.

See Video

#### Relevance Feedback

In real interactive CBIR systems, the user should be allowed to interact with the system to "refine" the results of a query until he/she is satisfied.

Relevance feedback work has been done by a number of research groups, e.g.

- The Photobook Project (Media Lab, MIT)
- The Leiden Portrait Retrieval Project
- The MARS Project (Tom Huang's group at Illinois)

#### Information Retrieval Model\*

- An IR model consists of:
  - a document model
  - a query model
  - a model for computing similarity between documents and the queries
- Term (keyword) weighting
- Relevance Feedback

<sup>\*</sup>from Rui, Huang, and Mehrotra's work

### Term weighting

- Term weight
  - assigning different weights for different keyword(terms) according their relative importance to the document
- define  $w_{ik}$  to be the weight for term  $t_k$ , k=1,2,...,N, in the document i
- document / can be represented as a weight vector in the term space

$$D_i = [w_{i1}; w_{i2}; ...; w_{iN}]$$

### Term weighting

The query Q also is a weight vector in the term space

$$Q = [w_{q1}; w_{q2}; ...; w_{qN}]$$

The similarity between D and Q

$$Sim(D,Q) = \frac{D \cdot Q}{\|D\| \|Q\|}$$

#### Using Relevance Feedback

- The CBIR system should automatically adjust the weight that were given by the user for the relevance of previously retrieved documents
- Most systems use a statistical method for adjusting the weights.

#### The Idea of Gaussian Normalization

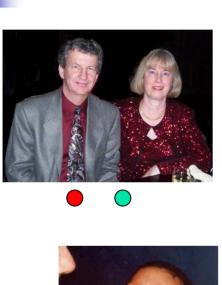

- If all the relevant images have similar values for component j
  - the component j is relevant to the query
- If all the relevant images have very different values for component j
  - the component j is not relevant to the query
- the inverse of the standard deviation of the related image sequence is a good measure of the weight for component j
- the smaller the variance, the larger the weight

# The Leiden Portrait System was an example of use of relevance feedback.

- The user was presented with a set of portraits on the screen
- Each portrait had a "yes" and "no" box under it, initialized to all "yes"
- The user would click "no" on the ones that were not the sort of portrait desired
- The system would repeat its search with the new feedback (multiple times if desired)

# Mockup of the Leiden System

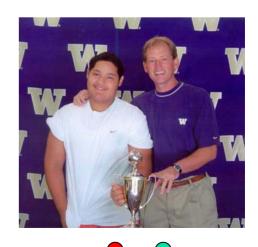

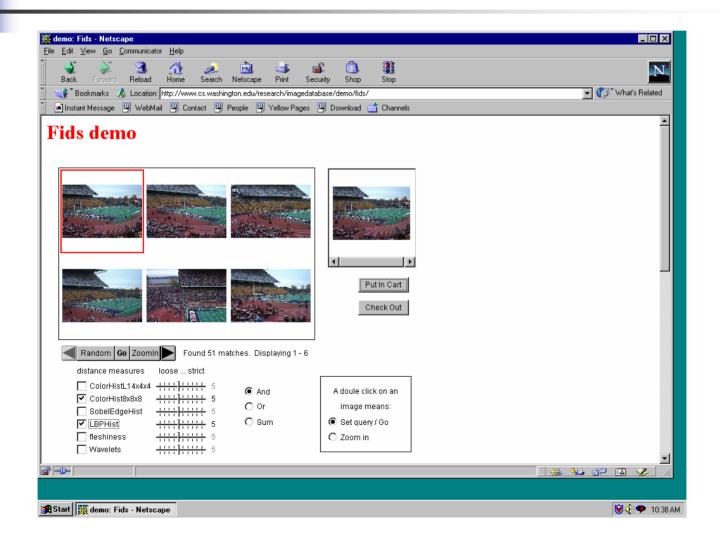

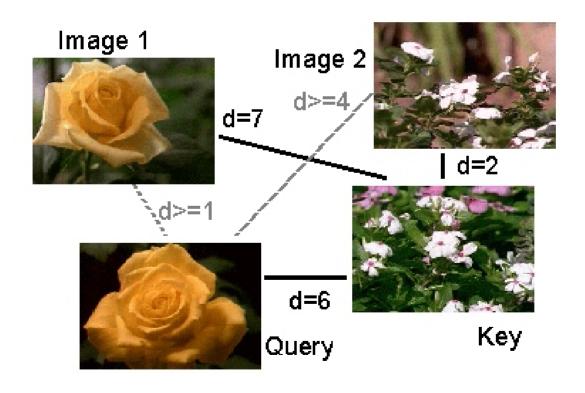

multiple distance measures
Boolean and linear combinations
efficient indexing using images as keys

Use of key images and the triangle inequality for efficient retrieval.

#### Bare-Bones Triangle Inequality Algorithm

#### Offline

- 1. Choose a small set of key images
- 2. Store distances from database images to keys

### Online (given query Q)

- 1. Compute the distance from Q to each key
- 2. Obtain lower bounds on distances to database images
- 3. Threshold or return all images in order of lower bounds

### Flexible Image Database System: Example

An example from our system using a simple color measure.

# images in system: 37,748 threshold: 100 out of 1000 # images eliminated: 37,729

#### Bare-Bones Algorithm with Multiple Distance Measures

#### Offline

- 1. Choose key images for each measure
- 2. Store distances from database images to keys for all measures

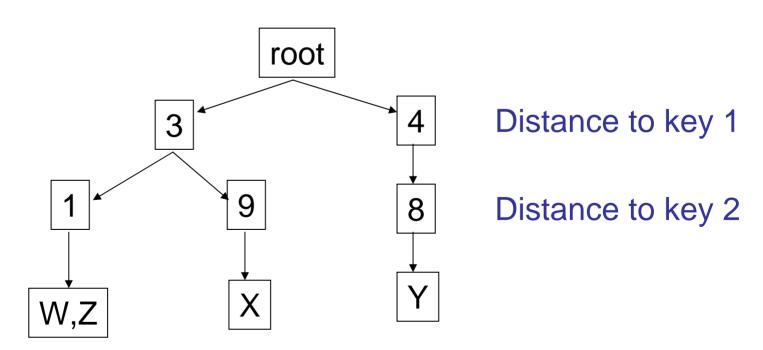

#### Online (given query Q)

- 1. Calculate lower bounds for each measure
- 2. Combine to form lower bounds for composite measures
- 3. Continue as in single measure algorithm

### **Triangle Tries**

A triangle trie is a tree structure that stores the distances from database images to each of the keys, one key per tree level.

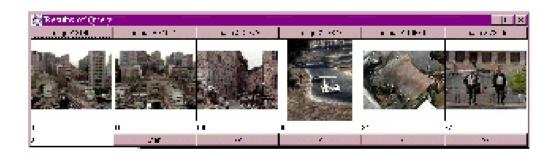

#### Triangle Tries and Two-Stage Pruning

- First Stage: Use a short triangle trie.
- Second Stage: Bare-bones algorithm on the images returned from the triangle-trie stage.

The quality of the output is the same as with the bare-bones algorithm itself, but execution is faster.

### Flexible Image Database System: Example

# of images in system: 37,748

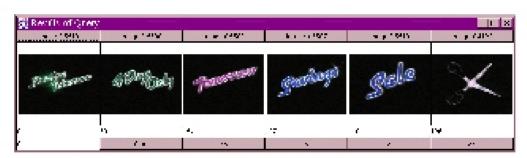

Depth of triangle trie: 6

# of images eliminated by trie: 30,300

# images eliminated by second-stage: 7429

19 images remaining, as before

Example from our system using a combination color+texture measure

#images in system: 37,748

#images from color trie: 3,676

# images from texture trie: 497

# images in merged set: 3,785

# images eliminated: 33,963

#### Performance on a Pentium Pro 200-mHz

- Step 1. Extract features from query image.  $(.02s \le t \le .25s)$
- Step 2. Calculate distance from query to key images.  $(1\mu s \le t \le .8ms)$
- Step 3. Calculate lower bound distances.

  (t ≈ 4ms per 1000 images using 35 keys, which is about 250,000 images per second.)
- Step 4. Return the images with smallest lower bound distances.

### Speed Comparisons

Image-query comparisons per second

<sup>^2</sup> digits of accuracy, not including key-comparison times.

<sup>🛮 35</sup> keys

<sup>\*</sup> Best trie found, depth and binning varies, threshold chosen by hand

### Demo of FIDS

http://www.cs.washington/research/ima gedatabase/demo

### Weakness of Low-level Features

Can't capture the high-level concepts

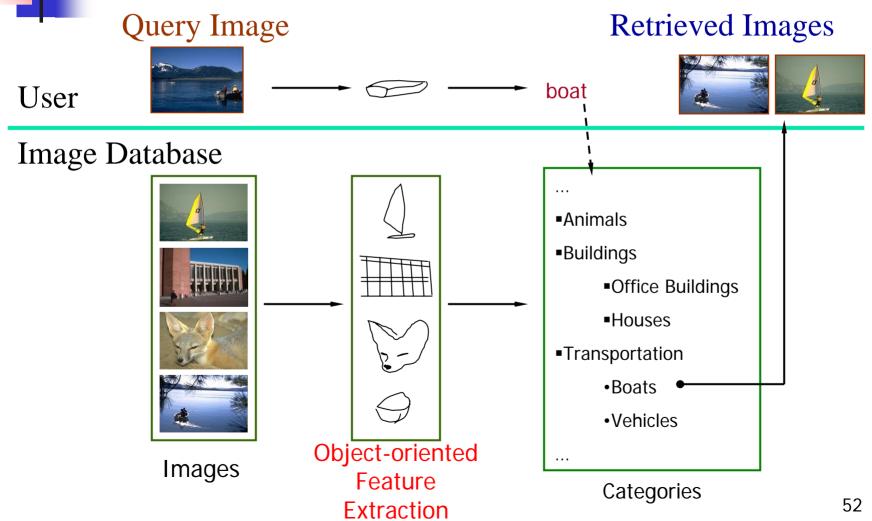

### Current Research Objective

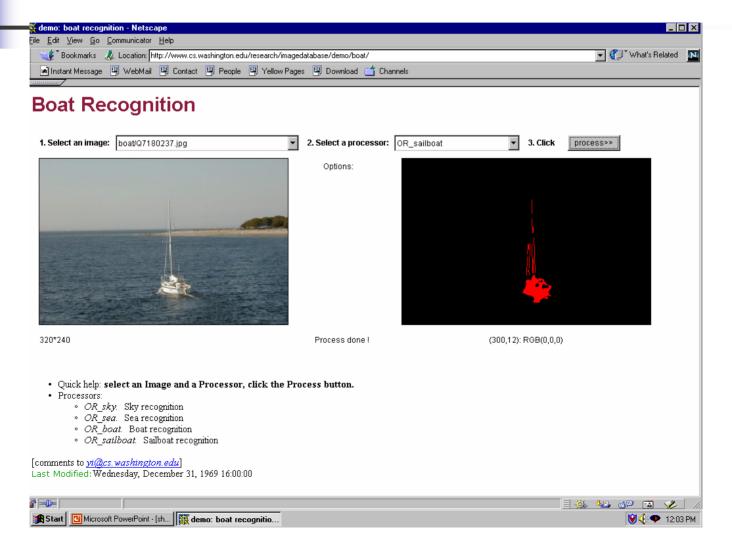

### Overall Approach

Develop object recognizers for common objects

 Use these recognizers to design a new set of both low- and mid-level features

 Design a learning system that can use these features to recognize classes of objects

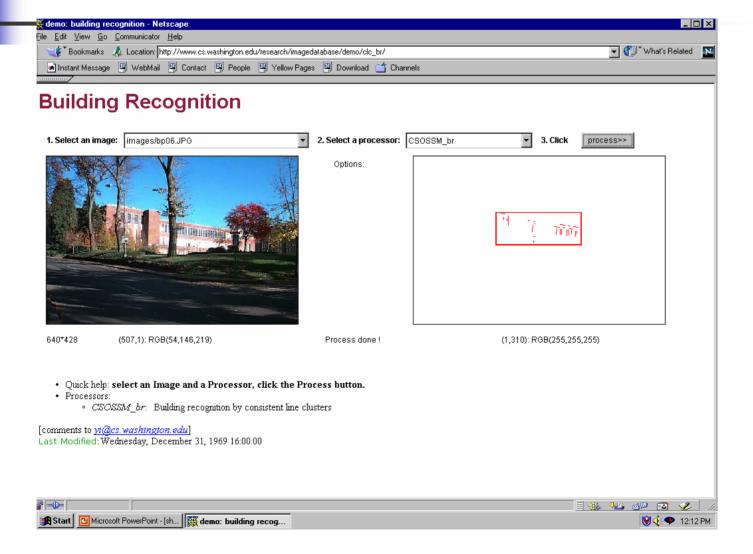

## **Boat Recognition**

# Vehicle Recognition

# **Building Recognition**

A Consistent Line Cluster is a set of lines that are homogeneous in terms of some line features.

•Color-CLC: The lines have the same color feature.

Orientation-CLC: The lines are parallel to each other or converge to a common vanishing point.

Spatially-CLC: The lines are in close proximity to each other.

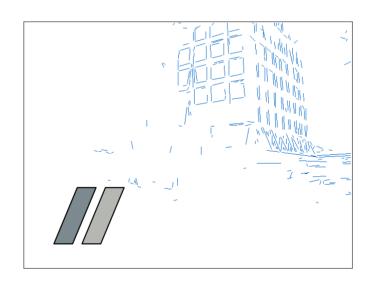

# Color-CLC

- Color feature of lines: color pair (c<sub>1</sub>,c<sub>2</sub>)
- Color pair space:
   RGB (256<sup>3</sup>\*256<sup>3</sup>) Too big!
   Dominant colors (20\*20)
- Finding the color pairs:
   One line → Several color pairs
- Constructing Color-CLC: use clustering

### Color-CLC

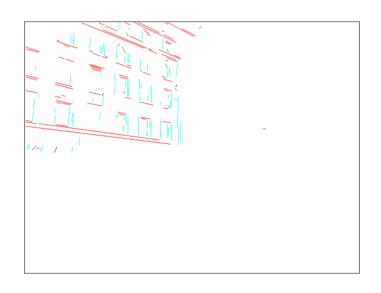

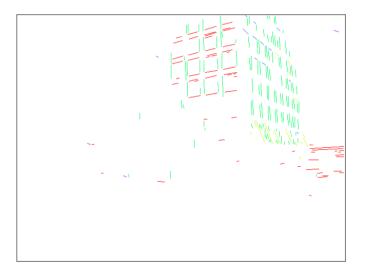

### Orientation-CLC

- The lines in an Orientation-CLC are parallel to each other in the 3D world
- The parallel lines of an object in a 2D image can be:
  - Parallel in 2D
  - Converging to a vanishing point (perspective)

## Spatially-CLC

- Vertical position clustering
- Horizontal position clustering

# **Building Recognition by CLC**

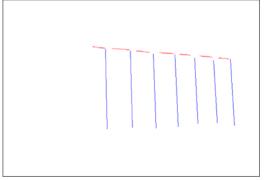

### Two types of buildings → Two criteria

- Inter-relationship criterion
- Intra-relationship criterion

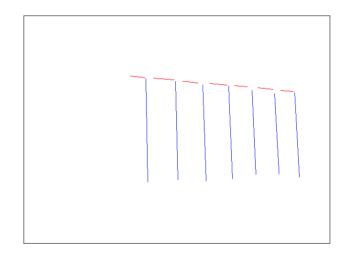

## Inter-relationship criterion

$$(N_{c1} > T_{i1} \text{ or } N_{c2} > T_{i1}) \text{ and } (N_{c1} + N_{c2}) > T_{i2}$$

 $N_{cl}$  = number of intersecting lines in cluster 1

 $N_{c2}$  = number of intersecting lines in cluster 2

### Intra-relationship criterion

$$|S_o| > T_{j1} \text{ or } W(S_o) > T_{j2}$$

 $S_0$  = set of heavily overlapping lines in a cluster

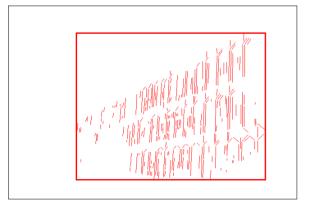

- Object Recognition
  - 97 well-patterned buildings (bp): 97/97
  - 44 not well-patterned buildings (bnp): 42/44
  - 16 not patterned non-buildings (nbnp): 15/16 (one false positive)
  - 25 patterned non-buildings (nbp): 0/25
- CBIR

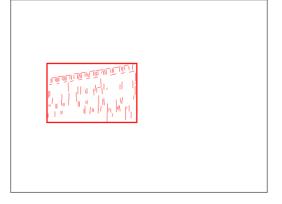

### Well-Patterned Buildings

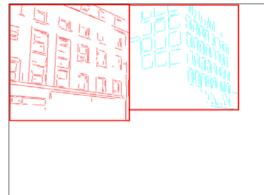

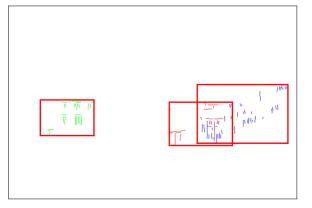

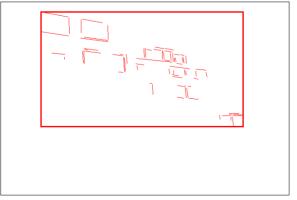

### Non-Well-Patterned Buildings

### Non-Well-Patterned Non-Buildings

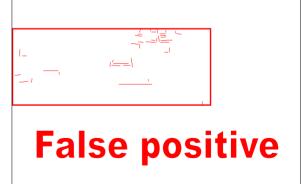

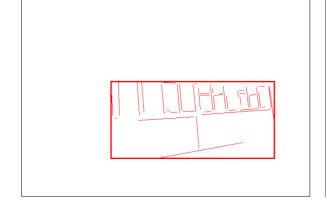

# ,

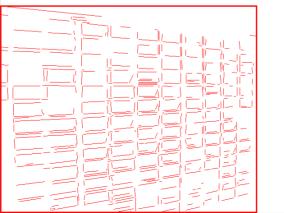

# Experimental Evaluation Well-Patterned Non-Buildings (false positives)

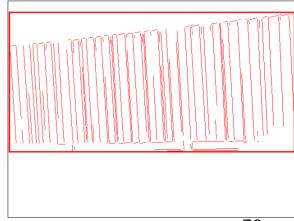

# Experimental Evaluation (CBIR)

### Experimental Evaluation (CBIR)

False positives from Yellowstone

### **Future Work**

- Future Work
  - Constructing hierarchically structured clusters
  - Using CLC on other objects
  - Combining CLC with other features
  - Developing a learning approach using hierarchical, multiple classifiers (Chou 2000)
