Reading

Forsyth & Ponce, chapter 8 (in reader)

What is an image?

Images as functions

We can think of an **image** as a function, f , from \mathbb{R}^2 to \mathbb{R} :

- $f(x,y)$ gives the **intensity** at position (x, y)
- Typically, the image is defined over a rectangle, and the range is finite:
 - $f: [a,b] \times [c,d] \rightarrow [0,1]$

A color image is just three functions pasted together.

We can write this as a “vector-valued” function:

$$f(x,y) = \begin{bmatrix} r(x,y) \\ g(x,y) \\ b(x,y) \end{bmatrix}$$

Digital image

In computer vision we usually operate on **digital (discrete)** images:

- **Sample** the 2D space on a regular grid
- **Quantize** each sample (round to nearest integer)

If our samples are Δ apart, we can write this as:

$$f[i,j] = \text{Quantize}\{ f(i\Delta, j\Delta) \}$$

The image can now be represented as an array of integer values

		→ j						
↓ i	62	79	23	119	120	105	4	0
10	10	9	62	12	78	34	0	
10	58	197	46	46	0	0	48	
176	135	5	188	191	68	0	49	
2	1	1	29	26	37	0	77	
0	89	144	147	187	102	62	208	
255	252	0	166	123	62	0	31	
166	63	127	17	1	0	99	30	

Image processing

An **image processing** operation typically defines a new image g in terms of an existing image f .

We can transform the domain and/or the range of f

Some operations preserve the domain but change the range of f :

$$g(x,y) = t(f(x,y))$$

Some operations preserve the range but change the domain of f :

$$g(x,y) = f(t_x(x,y), t_y(x,y))$$

Noise

Image processing is useful for noise reduction...

Common types of noise:

- **Salt and pepper noise:** contains random occurrences of black and white pixels
- **Impulse noise:** contains random occurrences of white pixels
- **Gaussian noise:** variations in intensity drawn from a Gaussian normal distribution

Noise reduction

How can we “smooth” away noise in an image?

	10	10	10	0	0	0	0	0		

Cross-correlation filtering

Let's write this down as an equation. Assume the averaging window is $(2k+1) \times (2k+1)$:

$$G[i, j] = \frac{1}{(2k+1)^2} \sum_{u=-k}^k \sum_{v=-k}^k F[i+u, j+v]$$

We can generalize this idea by allowing different weights for different neighboring pixels:

$$G[i, j] = \sum_{u=-k}^k \sum_{v=-k}^k H[u, v] F[i+u, j+v]$$

This is called a **cross-correlation** operation and written:

$$G = H \otimes F$$

H is called the “filter,” “kernel,” or “mask.”

The above allows negative filter indices. When you implement need to use: $H[u+k, v+k]$ instead of $H[u, v]$

Effect of mean filters

13

Mean kernel

What's the kernel for a 3x3 mean filter?

0	0	0	0	0	0	0	0	0	0
0	0	0	0	0	0	0	0	0	0

0	0	0	0	0	0	0
0	0	0	0	0	0	0

$F[x, y]$

$G[x, y]$

17

Convolution filtering

A **convolution** operation is a cross-correlation where the filter is flipped both horizontally and vertically before being applied to the image:

$$G[i, j] = \sum_{u=-k}^k \sum_{v=-k}^k H[u, v] F[i - u, j - v]$$

It is written:

$$G = H \star F$$

Suppose H is a Gaussian or mean kernel. How does convolution differ from cross-correlation?

Suppose F is an impulse function (previous slide) What will G look like?

Continuous filters

We can also apply filters to *continuous* images.

In the case of cross correlation: $g = h \otimes f$

$$g(x, y) = \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} h(u, v) f(x + u, y + v) du dv$$

In the case of convolution: $g = h \star f$

$$g(x, y) = \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} h(u, v) f(x - u, y - v) du dv$$

Note that the image and filter are infinite.

Median filters

A **Median Filter** operates over a window by selecting the median intensity in the window.

What advantage does a median filter have over a mean filter?

Is a median filter a kind of convolution?

Median filter

Try filtering this image with a 3x3 median
