Recognition

The "Margaret Thatcher Illusion", by Peter Thompson

Readings

- C. Bishop, "Neural Networks for Pattern Recognition", Oxford University Press, 1998, Chapter 1.
- Szeliski, Chapter 14.2.1 (eigenfaces)

What do we mean by "recognition"?

Next 15 slides adapted from Li, Fergus, & Torralba's excellent <u>short course</u> on category and object recognition

Recognition

The "Margaret Thatcher Illusion", by Peter Thompson

Verification: is that a lamp?

Detection: are there people?

Object categorization

Identification: is that Potala Palace?

Scene and context categorization

Applications: Computational photography

[Face priority AE] When a bright part of the face is too bright

Applications: Assisted driving

Pedestrian and car detection

Lane detection

- Collision warning systems with adaptive cruise control,
- Lane departure warning systems,
- Rear object detection systems,

Applications: image search

Challenges: viewpoint variation

Challenges: illumination variation

<text>

Challenges: deformation

Xu, Beihong 1943

Challenges: background clutter

Klimt, 1913

Face detection

How to tell if a face is present?

Challenges: intra-class variation

One simple method: skin detection

Skin pixels have a distinctive range of colors

- Corresponds to region(s) in RGB color space
 - for visualization, only R and G components are shown above

Skin classifier

- A pixel X = (R,G,B) is skin if it is in the skin region
- But how to find this region?

Skin detection

Learn the skin region from examples

- · Manually label pixels in one or more "training images" as skin or not skin
- Plot the training data in RGB space
 - skin pixels shown in orange, non-skin pixels shown in blue
 - some skin pixels may be outside the region, non-skin pixels inside. Why?

Skin classifier

• Given X = (R,G,B): how to determine if it is skin or not?

Skin classification techniques

Skin classifier: Given X = (R,G,B): how to determine if it is skin or not?

- Nearest neighbor
 - find labeled pixel closest to X
- · Find plane/curve that separates the two classes
 - popular approach: Support Vector Machines (SVM)
- Data modeling
 - fit a model (curve, surface, or volume) to each class
 - probabilistic version: fit a probability density/distribution model to each class

Probability

Basic probability

- X is a random variable
- P(X) is the probability that X achieves a certain value

Probabilistic skin classification

Now we can model uncertainty

• Each pixel has a probability of being skin or not skin $P(\sim \text{skin}|R) = 1 - P(\text{skin}|R)$

Skin classifier

- Given X = (R,G,B): how to determine if it is skin or not?
- Choose interpretation of highest probability
 - set X to be a skin pixel if and only if $\,R_1 < X \leq R_2\,$

Where do we get P(skin|R) and $P(\sim skin|R)$?

Learning conditional PDF's

We can calculate P(R | skin) from a set of training images

It is simply a histogram over the pixels in the training images
 – each bin R_i contains the proportion of skin pixels with color R_i

This doesn't work as well in higher-dimensional spaces. Why not?

Approach: fit parametric PDF functions • common choice is rotated Gaussian - center $c = \overline{X}$ - covariance $\sum_{X} (X - \overline{X})(X - \overline{X})^T$ » orientation, size defined by eigenvecs, eigenvals

Learning conditional PDF's

We can calculate P(R | skin) from a set of training images

- It is simply a histogram over the pixels in the training images – each bin R_{i} contains the proportion of skin pixels with color R_{i}

But this isn't quite what we want

- Why not? How to determine if a pixel is skin?
- We want P(skin | R) not P(R | skin)
- How can we get it?

Bayes rule

$$P(X|Y) = \frac{P(Y|X)P(X)}{P(Y)}$$

In terms of our problem:

what we measure domain knowledge (likelihood) (prior)

$$P(\mathsf{skin}|R) = \frac{P(R|\mathsf{skin}) P(\mathsf{skin})}{P(R)}$$

what we want (**posterior**)

normalization term $P(R) = P(R|\text{skin})P(\text{skin})+P(R| \sim \text{skin})P(\sim \text{skin})$

What could we use for the prior P(skin)?

- · Could use domain knowledge
 - P(skin) may be larger if we know the image contains a person
 - $-\,$ for a portrait, P(skin) may be higher for pixels in the center
- Could learn the prior from the training set. How?
 - P(skin) may be proportion of skin pixels in training set

Bayesian estimation

Bavesian estimation

= minimize probability of misclassification

Goal is to choose the label (skin or ~skin) that maximizes the posterior

 this is called Maximum A Posteriori (MAP) estimation

Skin detection results

Figure 25.3. The figure shows a variety of images together with the output of the skin detector of Jones and Rehg applied to the image. Pixels marked black are skin pixels, and white are background. Notice that this process is relatively effective, and could certainly be used to focus attention on, say, faces and hands. Figure from "Statistical color models with application to skin detection," M.J. Jones and J. Rehg, Proc. Computer Vision and Pattern Recognition, 1999 (1999, IEEE

General classification

This same procedure applies in more general circumstances

- More than two classes
- More than one dimension

Example: face detection

- Here, X is an image region
 - dimension = # pixels
 - each face can be thought of as a point in a high dimensional space

H. Schneiderman, T. Kanade. "A Statistical Method for 3D Object Detection Applied to Faces and Cars". IEEE Conference on Computer Vision and Pattern Recognition (CVPR 2000) http://www.2_cs.emu.edu/aiser/hws/www/CVPR00.pdf

H. Schneiderman and T.Kanade

Classification can be expensive

• Big search prob (e.g., nearest neighbors) or store large PDF's

Suppose the data points are arranged as above

· Idea-fit a line, classifier measures distance to line

Dimensionality reduction

Dimensionality reduction

- We can represent the orange points with only their v1 coordinates
 - since \boldsymbol{v}_2 coordinates are all essentially 0
- This makes it much cheaper to store and compare points
- A bigger deal for higher dimensional problems

Principal component analysis (PCA)

Suppose each data point is N-dimensional

· Same procedure applies:

$$\begin{array}{ll} \mathit{var}(\mathbf{v}) &=& \sum_{\mathbf{x}} \| (\mathbf{x} - \overline{\mathbf{x}})^{\mathrm{T}} \cdot \mathbf{v} \| \\ &=& \mathbf{v}^{\mathrm{T}} \mathbf{A} \mathbf{v} \ \ \, \text{where} \ \, \mathbf{A} = \sum_{\mathbf{x}} (\mathbf{x} - \overline{\mathbf{x}}) (\mathbf{x} - \overline{\mathbf{x}})^{\mathrm{T}} \end{array}$$

- · The eigenvectors of A define a new coordinate system
 - eigenvector with largest eigenvalue captures the most variation among training vectors \boldsymbol{x}
 - eigenvector with smallest eigenvalue has least variation
- · We can compress the data by only using the top few eigenvectors
 - corresponds to choosing a "linear subspace"
 - » represent points on a line, plane, or "hyper-plane"
 - these eigenvectors are known as the principal components

The space of faces

An image is a point in a high dimensional space

- An N x M image is a point in R^{NM}
- · We can define vectors in this space as we did in the 2D case

Dimensionality reduction

The set of faces is a "subspace" of the set of images

- Suppose it is K dimensional
- We can find the best subspace using PCA
- This is like fitting a "hyper-plane" to the set of faces
 - spanned by vectors $\mathbf{v}_1, \mathbf{v}_2, ..., \mathbf{v}_K$
 - any face $\mathbf{x} \approx \overline{\mathbf{x}} + a_1 \mathbf{v}_1 + a_2 \mathbf{v}_2 + \ldots + a_k \mathbf{v}_k$

Projecting onto the eigenfaces

The eigenfaces $\mathbf{v}_1, ..., \mathbf{v}_{\mathbf{K}}$ span the space of faces

A face is converted to eigenface coordinates by

$$\mathbf{x} \to (\underbrace{(\mathbf{x} - \overline{\mathbf{x}}) \cdot \mathbf{v}_1}_{a_1}, \underbrace{(\mathbf{x} - \overline{\mathbf{x}}) \cdot \mathbf{v}_2}_{a_2}, \dots, \underbrace{(\mathbf{x} - \overline{\mathbf{x}}) \cdot \mathbf{v}_K}_{a_K}$$

$$\mathbf{x} \approx \overline{\mathbf{x}} + a_1 \mathbf{v}_1 + a_2 \mathbf{v}_2 + \ldots + a_K \mathbf{v}_K$$

Eigenfaces

PCA extracts the eigenvectors of A

- Gives a set of vectors $\boldsymbol{v}_1,\,\boldsymbol{v}_2,\,\boldsymbol{v}_3,\,...$
- Each one of these vectors is a direction in face space

 what do these look like?

Recognition with eigenfaces

Algorithm

- 1. Process the image database (set of images with labels)
 - Run PCA—compute eigenfaces
 - Calculate the K coefficients for each image
- 2. Given a new image (to be recognized) $\boldsymbol{x},$ calculate K coefficients

$$\mathbf{x} \to (a_1, a_2, \dots, a_K)$$

3. Detect if x is a face

 $\|\mathbf{x} - (\mathbf{\overline{x}} + a_1\mathbf{v}_1 + a_2\mathbf{v}_2 + \ldots + a_K\mathbf{v}_K)\| < \text{threshold}$

- 4. If it is a face, who is it?
 - Find closest labeled face in database
 - nearest-neighbor in K-dimensional space
