# Why do we care about Geometry?

- Self-driving cars: navigation, collision avoidance
- Robots: navigation, manipulation
- Graphics & AR/VR: augment or generate images
- Photogrammetry (architecture, surveys)
- Pattern Recognition (web, medical imaging, etc)

2D & 3D Transformations

# Points in Cartesian and Homogeneous Coordinates

2D points:  $\mathbf{x} = (x, y) \in \mathcal{R}^2$  or column vector  $\mathbf{x} = \begin{bmatrix} x \\ y \end{bmatrix}$

3D points:  $\mathbf{x} = (x, y, z) \in \mathcal{R}^3$  (often noted  $\mathbf{X}$  or  $\mathbf{P}$ )

Homogeneous coordinates: append a 1

$$\bar{\mathbf{x}} = (x, y, 1) \qquad \bar{\mathbf{x}} = (x, y, z, 1)$$

Why?

# Homogeneous coordinates in 2D

2D Projective Space:  $\mathcal{P}^2 = \mathcal{R}^3 - (0, 0, 0)$  (same story in 3D with  $\mathcal{P}^3$ )

- heterogeneous  $\rightarrow$  homogeneous  $\begin{bmatrix} x \\ y \end{bmatrix} \Rightarrow \begin{bmatrix} x \\ y \\ 1 \end{bmatrix}$

- homogeneous  $\rightarrow$  heterogeneous  $\begin{bmatrix} x \\ y \\ w \end{bmatrix} \Rightarrow \begin{bmatrix} x/w \\ y/w \end{bmatrix}$

- points differing only by scale are *equivalent*:  $(x, y, w) \sim \lambda (x, y, w)$

$$\tilde{\mathbf{x}} = (\tilde{x}, \tilde{y}, \tilde{w}) = \tilde{w}(x, y, 1) = \tilde{w}\bar{\mathbf{x}}$$

# Homogeneous coordinates in 2D

In homogeneous coordinates, a point and its scaled versions are same

$$\begin{bmatrix} x \\ y \\ 1 \end{bmatrix} = w \begin{bmatrix} x \\ y \\ 1 \end{bmatrix} = \begin{bmatrix} wx \\ wy \\ w \end{bmatrix} \quad w \neq 0$$

# Everything is easier in Projective Space

2D Lines:

Representation:  $l = (a, b, c)$

Equation:  $ax + by + c = 0$

In homogeneous coordinates:  $\bar{x}^T l = 0$

General idea: homogenous coordinates  
unlock the full power of linear algebra!

# Everything is easier in Projective Space

2D Lines:

$$\tilde{\mathbf{x}}^T \mathbf{l} = 0, \forall \tilde{\mathbf{x}} = (x, y, w) \in P^2$$

$$\mathbf{l} = (\hat{n}_x, \hat{n}_y, d) = (\hat{\mathbf{n}}, d) \text{ with } \|\hat{\mathbf{n}}\| = 1$$

3D planes: same!

$$\tilde{\mathbf{x}}^T \mathbf{m} = 0, \forall \tilde{\mathbf{x}} = (x, y, z, w) \in P^3$$

$$\mathbf{m} = (\hat{n}_x, \hat{n}_y, \hat{n}_z, d) = (\hat{\mathbf{n}}, d) \text{ with } \|\hat{\mathbf{n}}\| = 1$$

# Lines in 3D

Two-point parametrization:

$$\mathbf{r} = (1 - \lambda)\mathbf{p} + \lambda\mathbf{q} \quad \tilde{\mathbf{r}} = \mu\tilde{\mathbf{p}} + \lambda\tilde{\mathbf{q}}$$

Two-plane parametrization:

coordinates  $(x_0, y_0)$  &  $(x_1, y_1)$  of intersection

with planes at  $z = 0, 1$  (or other planes)

# Cross-product quick reminder

$$\mathbf{a} \times \mathbf{b} = \|\mathbf{a}\| \|\mathbf{b}\| \sin(\theta) \mathbf{n}$$

$$\mathbf{a} \times \mathbf{b} = [\mathbf{a}]_{\times} \mathbf{b} = \begin{bmatrix} 0 & -a_3 & a_2 \\ a_3 & 0 & -a_1 \\ -a_2 & a_1 & 0 \end{bmatrix} \begin{bmatrix} b_1 \\ b_2 \\ b_3 \end{bmatrix}$$

# Benefits of Homogeneous Coordinates

- Line – Point duality:
  - line between two 2D points:  $\tilde{\mathbf{l}} = \tilde{\mathbf{x}}_1 \times \tilde{\mathbf{x}}_2$
  - intersection of two 2D lines:  $\tilde{\mathbf{x}} = \tilde{\mathbf{l}}_1 \times \tilde{\mathbf{l}}_2$
- Representation of Infinity:
  - points at infinity:  $(x, y, 0)$ ; line at infinity:  $(0, 0, 1)$
- Parallel & vertical lines are easy (take-home: intersect //)
- Makes 2D & 3D transformations linear!

# Affine Transformation

This matrix is a linear transformation matrix in 3D

$$\begin{bmatrix} x' \\ y' \\ 1 \end{bmatrix} = \begin{bmatrix} A_{00} & A_{01} & b_0 \\ A_{10} & A_{11} & b_1 \\ 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} x \\ y \\ 1 \end{bmatrix}$$

Then this column is the third basis vector of transformed vector space

And what  $b_0$  and  $b_1$  do is to change the orientation of that basis vector

# Affine Transformation

# Affine Transformation

# Affine Transformation

# Affine Transformation

# Affine Transformation

Affine transformations are combinations of

- Arbitrary (4-DOF) linear transformations + translations

Properties of affine transformations:

- **origin does not necessarily map to origin**
- lines map to lines
- parallel lines map to parallel lines
- ratios are preserved

$$\begin{bmatrix} x' \\ y' \\ 1 \end{bmatrix} = \begin{bmatrix} A_{00} & A_{01} & b_0 \\ A_{10} & A_{11} & b_1 \\ 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} x \\ y \\ 1 \end{bmatrix}$$

# Projective Transformation (homography)

Projective transformations are combinations of

# Composing Transformations

Transformations = Matrices => Composition by Multiplication!

$$p' = R_2 R_1 S p$$

In the example above, the result is equivalent to

$$p' = R_2 (R_1 (S p))$$

Equivalent to multiply the matrices into single transformation matrix:

$$p' = (R_2 R_1 S) p$$

Order Matters! Transformations from *right to left*.

# Scaling & Translating != Translating & Scaling

**Axis-angle:**  $(\hat{n}, \theta)$  or  $\omega = \theta \hat{n}$

→ matrix via Rodrigues formula (simple for small  $\theta$ )

$$\mathbf{R}(\hat{n}, \theta) = \mathbf{I} + \sin \theta [\hat{n}]_{\times} + (1 - \cos \theta) [\hat{n}]_{\times}^2 \approx \mathbf{I} + [\theta \hat{n}]_{\times}$$

**Unit Quaternions:**  $\mathbf{q} = (x, y, z, w) = (\sin \frac{\theta}{2} \hat{n}, \cos \frac{\theta}{2})$ ,  $\|\mathbf{q}\| = 1$

→ continuous, nice algebraic properties, matrix via Rodrigues

$$\mathbf{R}(\mathbf{q}) = \begin{bmatrix} 1 - 2(y^2 + z^2) & 2(xy - zw) & 2(xz + yw) \\ 2(xy + zw) & 1 - 2(x^2 + z^2) & 2(yz - xw) \\ 2(xz - yw) & 2(yz + xw) & 1 - 2(x^2 + y^2) \end{bmatrix}$$

**Polar coordinates...**

$$x = r \cos(\varphi)$$

$$y = r \sin(\varphi)$$

$$x' = r \cos(\varphi + \theta)$$

$$y' = r \sin(\varphi + \theta)$$

**Trigonometric Identity...**

$$x' = r \cos(\varphi) \cos(\theta) - r \sin(\varphi) \sin(\theta)$$

$$y' = r \sin(\varphi) \cos(\theta) + r \cos(\varphi) \sin(\theta)$$

**Substitute...**

$$x' = x \cos(\theta) - y \sin(\theta)$$

$$y' = x \sin(\theta) + y \cos(\theta)$$
