Reading

Required reading:

 Angel 3.1-3.11 (Geometric Objects and Transformations: Scalars, Points, and Vectors through Transformation Matrices in OpenGL)

Optional reading:

- Angel 3.12-3.14
- Foley, et al, Chapter 5.1-5.5.
- David F. Rogers and J. Alan Adams, *Mathematical Elements for Computer Graphics*, 2nd Ed., McGraw-Hill, New York, 1990, Chapter 2.

2

Linear Interpolation

3

More Interpolation

Geometric transformations

Geometric transformations will map points in one space to points in another: (x', y', z') = f(x, y, z).

These transformations can be very simple, such as scaling each coordinate, or complex, such as non-linear twists and bends.

We'll focus on transformations that can be represented easily with matrix operations.

5

Vector representation

We can represent a **point**, $\mathbf{p} = (x,y)$, in the plane or $\mathbf{p} = (x,y,z)$ in 3D space

as column vectors

$$\begin{bmatrix} x \\ y \end{bmatrix} \quad \begin{bmatrix} x \\ y \\ z \end{bmatrix}$$

as row vectors

$$\begin{bmatrix} x & y \end{bmatrix}$$
$$\begin{bmatrix} x & y & z \end{bmatrix}$$

6

Canonical axes

7

Vector length and dot products

Vector cross products

Inverse & Transpose

Representation, cont.

We can represent a **2-D transformation** M by a matrix

$$\begin{bmatrix} a & b \\ c & d \end{bmatrix}$$

If \mathbf{p} is a column vector, M goes on the left:

$$\mathbf{p'} = M\mathbf{p}$$

$$\begin{bmatrix} x' \\ y' \end{bmatrix} = \begin{bmatrix} a & b \\ c & d \end{bmatrix} \begin{bmatrix} x \\ y \end{bmatrix}$$

If **p** is a row vector, M^T goes on the right:

$$\mathbf{p'} = \mathbf{p} M^{T}$$

$$\begin{bmatrix} x' & y' \end{bmatrix} = \begin{bmatrix} x & y \end{bmatrix} \begin{bmatrix} a & c \\ b & d \end{bmatrix}$$

We will use column vectors.

11

Two-dimensional transformations

Here's all you get with a 2 x 2 transformation matrix *M*:

$$\begin{bmatrix} x' \\ y' \end{bmatrix} = \begin{bmatrix} a & b \\ c & d \end{bmatrix} \begin{bmatrix} x \\ y \end{bmatrix}$$

10

So:

$$x' = ax + by$$

 $y' = cx + dy$

We will develop some intimacy with the elements a, b, c, d...

Identity

Suppose we choose *a=d=1*, *b=c=0*:

• Gives the identity matrix:

Doesn't move the points at all

13

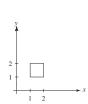

Scaling

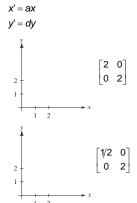

Suppose we set *b*=*c*=*0*, but let *a* and *d* take on any *positive* value:

• Gives a scaling matrix:

$$\begin{bmatrix} a & 0 \\ 0 & d \end{bmatrix}$$

 Provides differential (non-uniform) scaling in x and y:

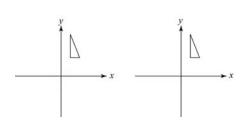

Suppose we keep b=c=0, but let either a or d go negative.

Examples:

$$\begin{bmatrix} -1 & 0 \\ 0 & 1 \end{bmatrix}$$

$$\begin{bmatrix} 1 & 0 \\ 0 & -1 \end{bmatrix}$$

15

Now let's leave a=d=1 and experiment with b...

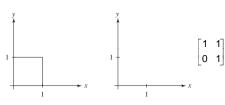

14

The matrix

$$\begin{bmatrix} 1 & b \\ 0 & 1 \end{bmatrix}$$

gives:

$$x' = x + by$$
$$y' = y$$

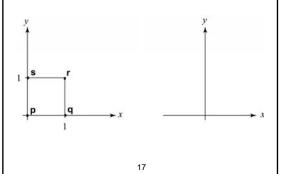

Effect on unit square

Let's see how a general 2 x 2 transformation *M* affects the unit square:

$$\begin{bmatrix} a & b \\ c & d \end{bmatrix} [\mathbf{p} \quad \mathbf{q} \quad \mathbf{r} \quad \mathbf{s}] = \begin{bmatrix} \mathbf{p'} \quad \mathbf{q'} \quad \mathbf{r'} \quad \mathbf{s'} \end{bmatrix}$$

$$\begin{bmatrix} a & b \\ c & d \end{bmatrix} \begin{bmatrix} 0 & 1 & 1 & 0 \\ 0 & 0 & 1 & 1 \end{bmatrix} = \begin{bmatrix} 0 & a & a+b & b \\ 0 & c & c+d & d \end{bmatrix}$$

Effect on unit square, cont.

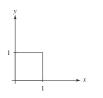

Observe:

- Origin invariant under M
- M can be determined just by knowing how the corners (1,0) and (0,1) are mapped
- a and d give x- and y-scaling
- b and c give x- and y-shearing

18

Rotation

From our observations of the effect on the unit square, it should be easy to write down a matrix for "rotation about the origin":

 $\bullet \begin{bmatrix} 0 \\ 1 \end{bmatrix} \rightarrow$

Thus

$$M = R(\theta) = \begin{bmatrix} \\ \\ \end{bmatrix}$$

Limitations of the 2 x 2 matrix

A 2 x 2 linear transformation matrix allows

- Scaling
- Rotation
- Reflection
- Shearing

Q: What important operation does that leave out?

Homogeneous coordinates

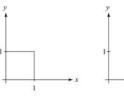

We can loft the problem up into 3-space, adding a third component to every point:

$$\begin{bmatrix} x \\ y \end{bmatrix} \rightarrow \begin{bmatrix} x \\ y \\ 1 \end{bmatrix}$$

Adding the third "w" component puts us in homogenous coordinates.

Then, transform with a 3 x 3 matrix:

$$\begin{bmatrix} x' \\ y' \\ w' \end{bmatrix} = T(\mathbf{t}) \begin{bmatrix} x \\ y \\ 1 \end{bmatrix} = \begin{bmatrix} 1 & 0 & t_x \\ 0 & 1 & t_y \\ 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} x \\ y \\ 1 \end{bmatrix}$$

... gives translation!

21

Affine transformations

The addition of translation to linear transformations gives us **affine transformations**.

In matrix form, 2D affine transformations always look like this:

$$M = \begin{bmatrix} a & b & t_x \\ c & d & t_y \\ 0 & 0 & 1 \end{bmatrix} = \begin{bmatrix} \mathbf{A} & \mathbf{t} \\ 0 & 0 & 1 \end{bmatrix}$$

2D affine transformations always have a bottom row of [0 0 1].

An "affine point" is a "linear point" with an added w-coordinate which is always 1:

$$\mathbf{p}_{\mathsf{aff}} = \begin{bmatrix} \mathbf{p}_{\mathsf{lin}} \\ 1 \end{bmatrix} = \begin{bmatrix} x \\ y \\ 1 \end{bmatrix}$$

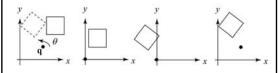

Applying an affine transformation gives another affine point:

$$M\mathbf{p}_{aff} = \begin{bmatrix} A\mathbf{p}_{lin} + \mathbf{t} \\ 1 \end{bmatrix}$$

Rotation about arbitrary points

Until now, we have only considered rotation about the origin.

With homogeneous coordinates, you can specify a rotation, θ , about any point $\mathbf{q} = [\mathbf{q_X} \ \mathbf{q_y} \ 1]^T$ with a matrix:

- 1. Translate q to origin
- 2. Rotate
- 3. Translate back

Note: Transformation order is important!!

23

Points and vectors

Vectors have an additional coordinate of w=0. Thus, a change of origin has no effect on vectors.

Q: What happens if we multiply a vector by an affine matrix?

These representations reflect some of the rules of affine operations on points and vectors:

vector + vector →

 $scalar \cdot vector \rightarrow$

point - point \rightarrow

point + vector →

point + point

One useful combination of affine operations is:

$$\mathbf{p}(t) = \mathbf{p}_o + t\mathbf{u}$$

Q: What does this describe?

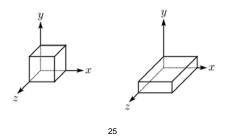

Basic 3-D transformations: scaling

Some of the 3-D affine transformations are just like the 2-D ones.

In this case, the bottom row is always [0 0 0 1].

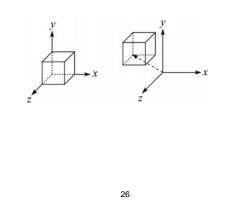

For example, scaling:

$$\begin{bmatrix} x' \\ y' \\ z' \\ 1 \end{bmatrix} = \begin{bmatrix} s_x & 0 & 0 & 0 \\ 0 & s_y & 0 & 0 \\ 0 & 0 & s_z & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} x' \\ y \\ z \end{bmatrix}$$

Translation in 3D

$$\begin{bmatrix} x' \\ y' \\ z' \\ 1 \end{bmatrix} = \begin{bmatrix} 1 & 0 & 0 & t_x \\ 0 & 1 & 0 & t_y \\ 0 & 0 & 1 & t_z \\ 0 & 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} x \\ y \\ z \\ 1 \end{bmatrix}$$

Rotation in 3D

Rotation now has more possibilities in 3D:

$$R_{\mathbf{X}}(\alpha) = \begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & \cos\alpha & -\sin\alpha & 0 \\ 0 & \sin\alpha & \cos\alpha & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix}$$

$$R_{\mathbf{Y}}(\beta) = \begin{bmatrix} \cos\beta & 0 & \sin\beta & 0 \\ 0 & 1 & 0 & 0 \\ -\sin\beta & 0 & \cos\beta & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix}$$

$$R_{\mathbf{Z}}(\gamma) = \begin{bmatrix} \cos\gamma & -\sin\gamma & 0 & 0 \\ \sin\gamma & \cos\gamma & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix}$$
Use right hand rule
$$0 = 0 = 0$$

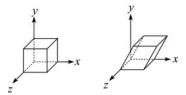

A general rotation can be specified in terms of a prodcut of these three matrices. How else might you specify a rotation?

27

Shearing in 3D

Shearing is also more complicated. Here is one example:

$$\begin{bmatrix} x' \\ y' \\ z' \\ 1 \end{bmatrix} = \begin{bmatrix} 1 & b & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} x' \\ y \\ z \\ 1 \end{bmatrix}$$

We call this a shear with respect to the x-z plane.

Properties of affine transformations

Here are some useful properties of affine transformations:

- · Lines map to lines
- Parallel lines remain parallel
- Midpoints map to midpoints (in fact, ratios are always preserved)

ratio =
$$\frac{\|\mathbf{pq}\|}{\|\mathbf{qr}\|} = \frac{s}{t} = \frac{\|\mathbf{p'q'}\|}{\|\mathbf{q'r'}\|}$$

29

Affine transformations in OpenGL

OpenGL maintains a "modelview" matrix that holds the current transformation $\boldsymbol{M}\boldsymbol{.}$

The modelview matrix is applied to points (usually vertices of polygons) before drawing.

It is modified by commands including:

- ◆ glLoadIdentity() M ← I- set M to identity
- $\begin{tabular}{ll} \bullet & \texttt{glTranslatef}(\texttt{t}_{\texttt{x}}, \texttt{t}_{\texttt{y}}, \texttt{t}_{\texttt{z}}) & \textbf{M} \leftarrow \textbf{MT} \\ & \textit{translate by}(\texttt{t}_{\texttt{x}}, \texttt{t}_{\texttt{y}}, \texttt{t}_{\texttt{z}}) & \end{tabular}$
- glRotatef (θ, x, y, z)
 M ← MR
 rotate by angle θ about axis (x, y, z)

Note that OpenGL adds transformations by postmultiplication of the modelview matrix.

30

Summary

What to take away from this lecture:

- All the names in boldface.
- How points and transformations are represented.
- How to compute lengths, dot products, and cross products of vectors, and what their geometrical meanings are.
- What all the elements of a 2 x 2 transformation matrix do and how these generalize to 3 x 3 transformations.
- What homogeneous coordinates are and how they work for affine transformations.
- · How to concatenate transformations.
- The mathematical properties of affine transformations.
