CSE 461: Computer networks

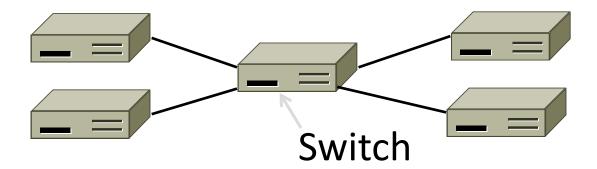

Spring 2021

Ratul Mahajan

Link Layer: Switching

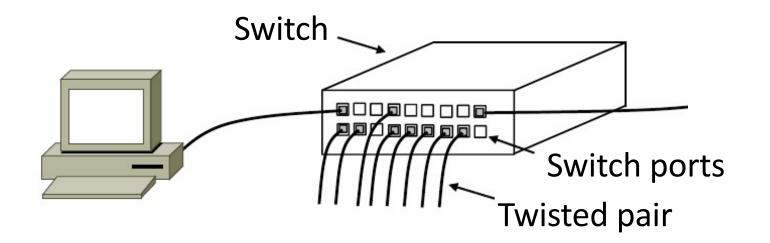

Switching

- How do we connect nodes with a <u>switch</u> instead of multiple access
 - Uses multiple links/wires
 - Basis of modern (switched) Ethernet

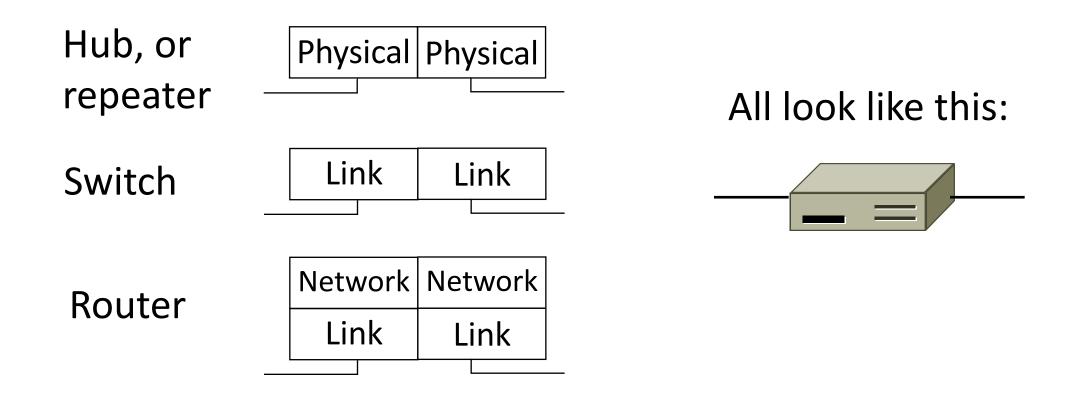

Switched Ethernet

- Hosts are wired to Ethernet switches with twisted pair
 - Switch serves to connect the hosts
 - Wires usually run to a closet

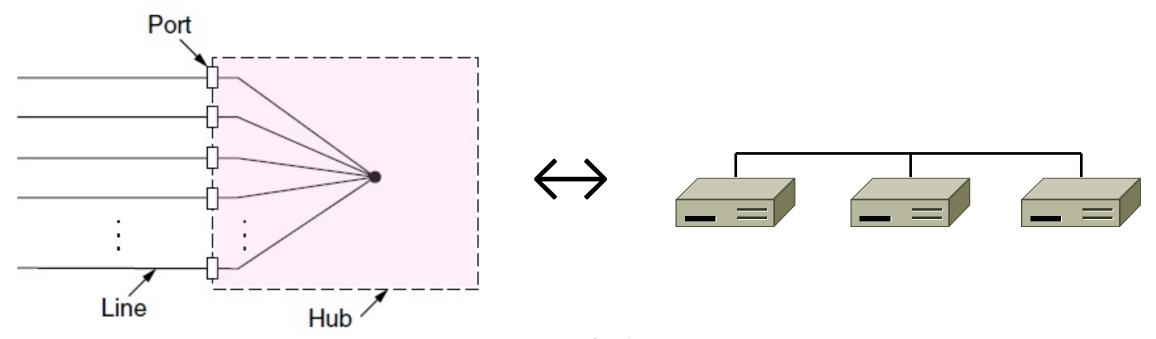

What's in the box?

Remember from protocol layers:

Inside a Hub

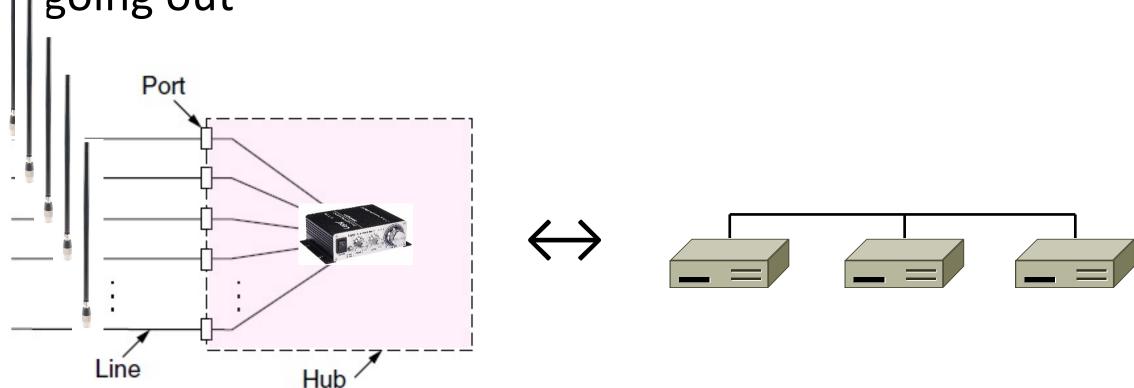

• All ports are wired together; more convenient and reliable than a single shared wire

CSE 461 University of Washington

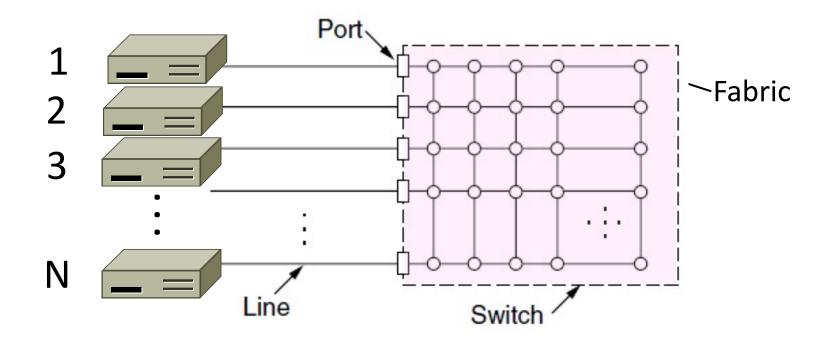

Inside a Repeater

All inputs are connected; then amplified before going out

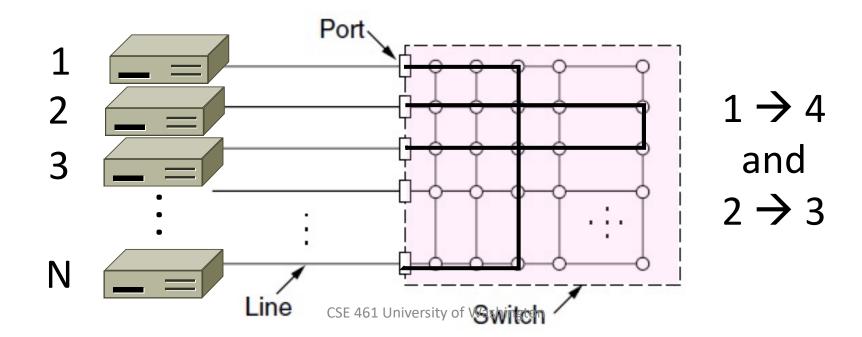

Inside a Switch

 Uses frame addresses (MAC addresses in Ethernet) to connect input port to the right output port; multiple frames may be switched in parallel

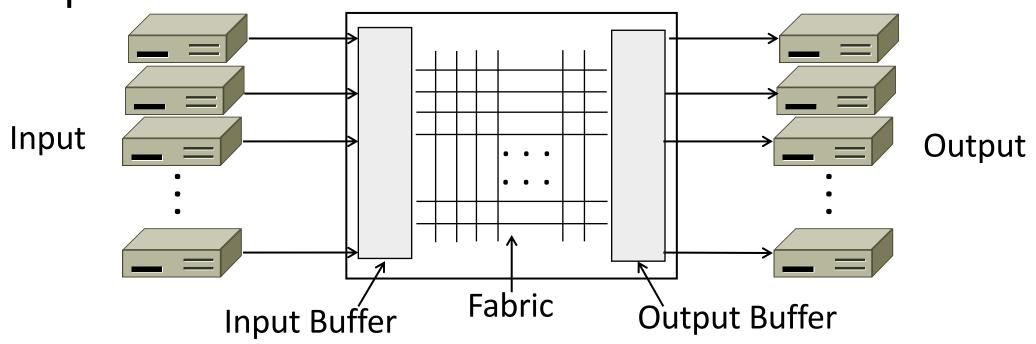

Inside a Switch (2)

- Port may be used for both input and output (full-duplex)
 - Just send, no multiple access protocol

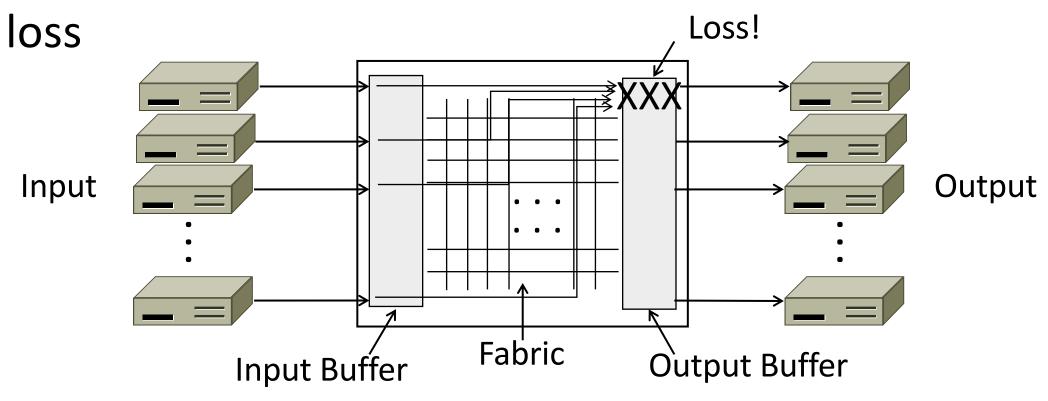

Inside a Switch (3)

Need buffers for multiple inputs to send to one output

Inside a Switch (4)

Sustained overload will fill buffer and lead to frame

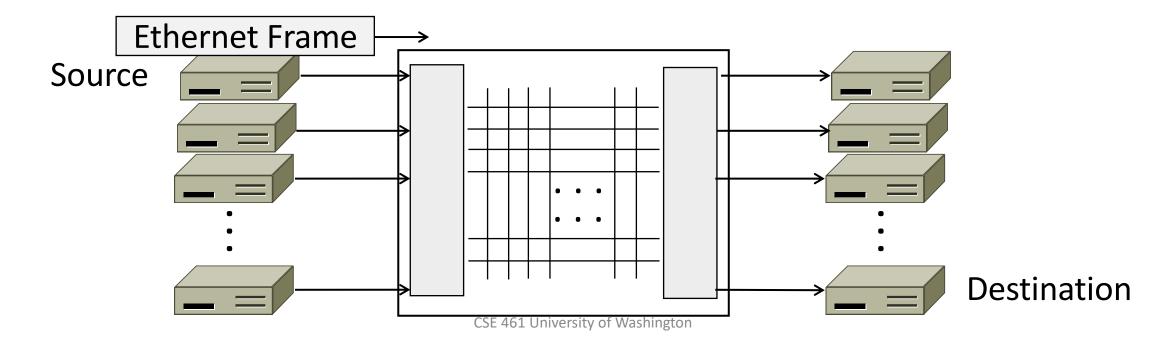

Advantages of Switches

- Switches and hubs (mostly switches) have replaced the shared cable of classic Ethernet
 - Convenient to run wires to one location
 - More reliable; wire cut is not a single point of failure that is hard to find
- Switches offer scalable performance
 - E.g., 100 Mbps per port instead of 100 Mbps for all nodes of shared cable / hub

Switch Forwarding

- Switch needs to find the right output port for the destination address in the Ethernet frame. How?
 - Link-level, don't look at IP

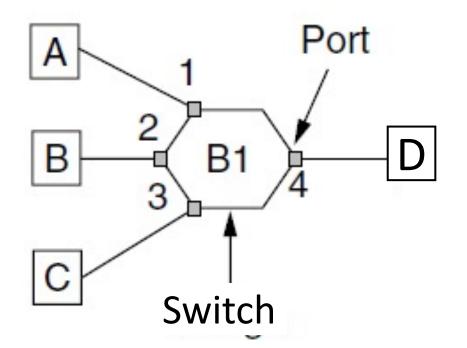

Backward Learning

- Switch forwards frames with a port/address table as follows:
 - 1. To fill the table, it looks at the source address of input frames
 - 2. To forward, it sends to the port, or else broadcasts to all ports

Backward Learning (2)

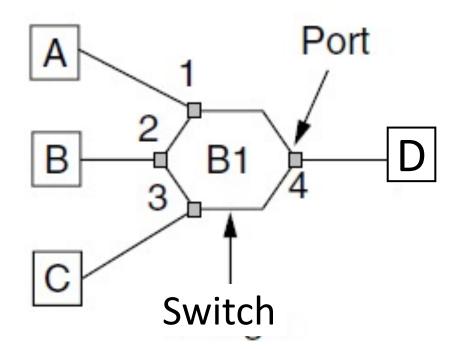

• 1: A sends to D

Address	Port
Α	
В	
С	
D	

Backward Learning (3)

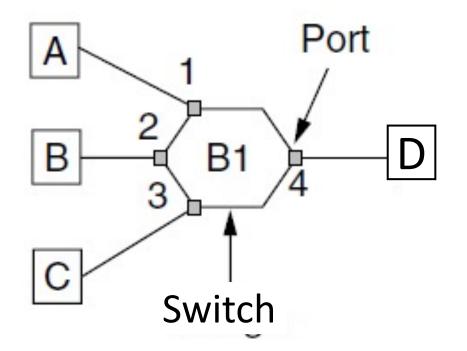

• 2: D sends to A

Address	Port
Α	1
В	
С	
D	

Backward Learning (4)

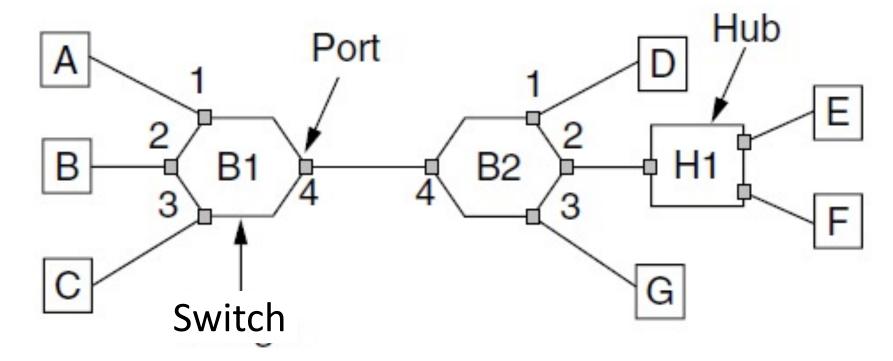

• 3: A sends to D

Address	Port
Α	1
В	
С	
D	4

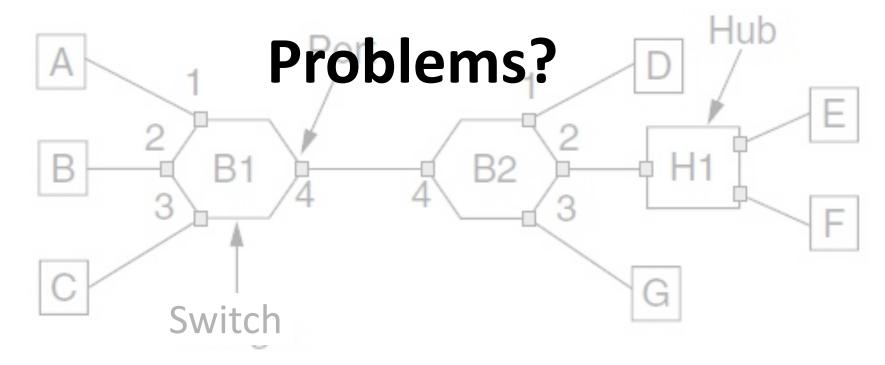

Learning with Multiple Switches

Just works with multiple switches and a mix of hubs,
 e.g., A -> D then D -> A

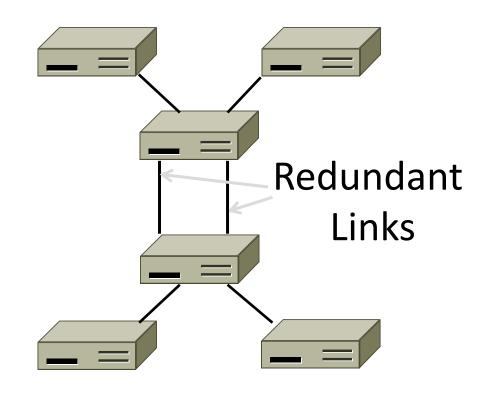

Learning with Multiple Switches

Just works with multiple switches and a mix of hubs,
 e.g., A -> D then D -> A

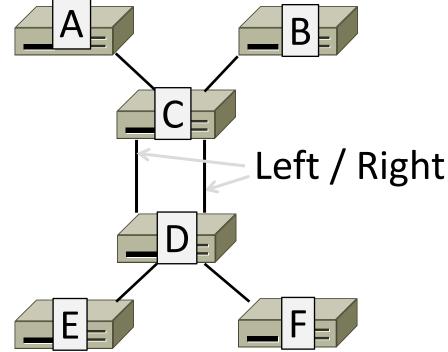

Problem – Forwarding Loops

- May have a loop in the topology
 - Redundancy in case of failures
 - Or a simple mistake
- Want LAN switches to "just work"
 - Plug-and-play, no changes to hosts
 - But loops cause a problem ...

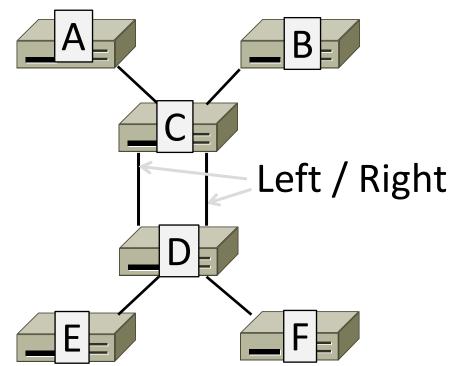

Forwarding Loops (2)

 Suppose the network is started and A sends to F. What happens?

Forwarding Loops (3)

- Suppose the network is started and A sends to F.
 What happens?
 - A \rightarrow C \rightarrow B, D-left, D-right
 - D-left → C-right, E, F
 - D-right → C-left, E, F
 - C-right → D-left, A, B
 - C-left → D-right, A, B
 - D-left → ...
 - D-right → ...

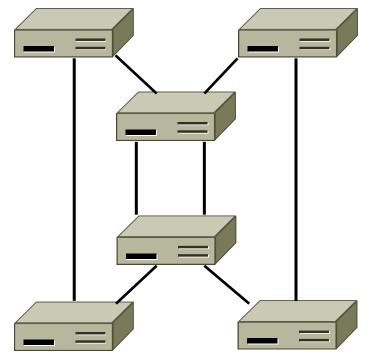

Spanning Tree Solution

- Switches collectively find a <u>spanning tree</u> for the topology
 - A subset of links that is a tree (no loops) and reaches all switches
 - They switches forward as normal on the spanning tree
 - Broadcasts will go up to the root of the tree and down all the branches

Spanning Tree (2)

Topology One ST

Spanning Tree (3)

Topology One ST **Another ST** Root

Spanning Tree Algorithm

- Rules of the distributed game:
 - All switches run the same algorithm
 - They start with no information
 - Operate in parallel and send messages
 - Always search for the best solution
- Ensures a highly robust solution
 - Any topology, with no configuration
 - Adapts to link/switch failures, ...

Radia Perlman (1952–)

- Key early work on routing protocols
 - Routing in the ARPANET
 - Spanning Tree for switches (next)
- Now focused on network security

Spanning Tree Algorithm (2)

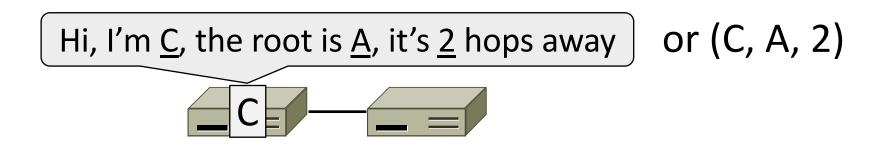

• Outline:

- 1. Elect a root node of the tree (switch with the lowest address)
- 2. Grow tree as shortest distances from the root (using lowest address to break distance ties)
- 3. Turn off ports for forwarding if they aren't on the spanning tree

Spanning Tree Algorithm (3)

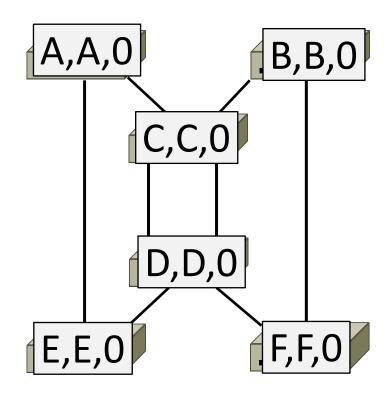

Details:

- Each switch initially believes it is the root of the tree
- Each switch sends periodic updates to neighbors with:
 - Its address, address of the root, and distance (in hops) to root
 - Short-circuit when topology changes
- Switches favors ports with shorter distances to lowest root
 - Uses lowest address as a tie for distances

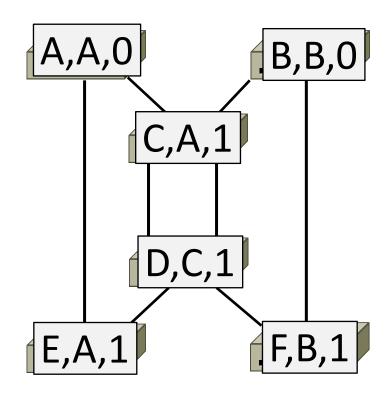

Spanning Tree Example

- 1st round, sending:
 - A sends (A, A, 0) to say it is root
 - B, C, D, E, and F do likewise
- 1st round, receiving:
 - A still thinks is it (A, A, 0)
 - B still thinks (B, B, 0)
 - C updates to (C, A, 1)
 - D updates to (D, C, 1)
 - E updates to (E, A, 1)
 - F updates to (F, B, 1)

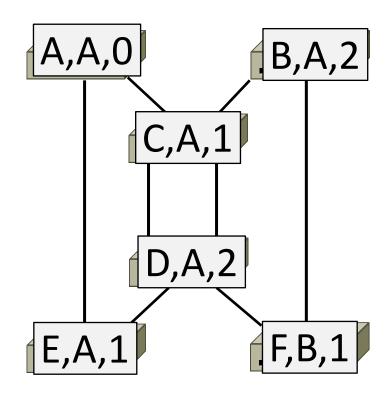

Spanning Tree Example (2)

- 2nd round, sending
 - Nodes send their updated state
- 2nd round receiving:
 - A remains (A, A, 0)
 - B updates to (B, A, 2) via C
 - C remains (C, A, 1)
 - D updates to (D, A, 2) via C
 - E remains (E, A, 1)
 - F remains (F, B, 1)

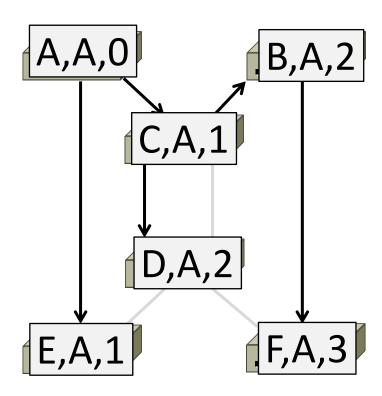

Spanning Tree Example (3)

- 3rd round, sending
 - Nodes send their updated state
- 3rd round receiving:
 - A remains (A, A, 0)
 - B remains (B, A, 2) via C
 - C remains (C, A, 1)
 - D remains (D, A, 2) via C-left
 - E remains (E, A, 1)
 - F updates to (F, A, 3) via B

Spanning Tree Example (4)

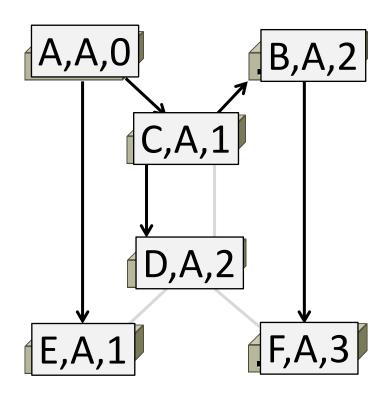

- 4th round
 - Steady-state has been reached
 - Nodes turn off forwarding that is not on the spanning tree
- Algorithm continues to run
 - Adapts by timing out information
 - E.g., if A fails, other nodes forget it, and B will become the new root

Spanning Tree Example (5)

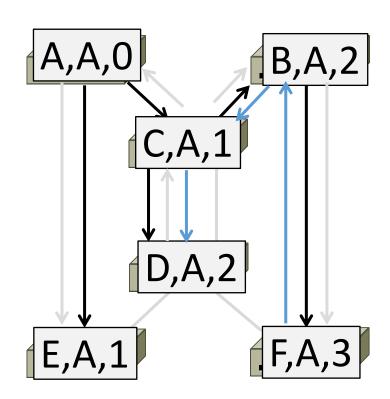

- Forwarding proceeds as usual on the ST
- Initially D sends to F:

• And F sends back to D:

Spanning Tree Example (6)

- Forwarding proceeds as usual on the ST
- Initially D sends to F:
 - D \rightarrow C-left
 - $C \rightarrow A, B$
 - $A \rightarrow E$
 - $B \rightarrow F$
- And F sends back to D:
 - $F \rightarrow B$
 - $B \rightarrow C$
 - $C \rightarrow D$

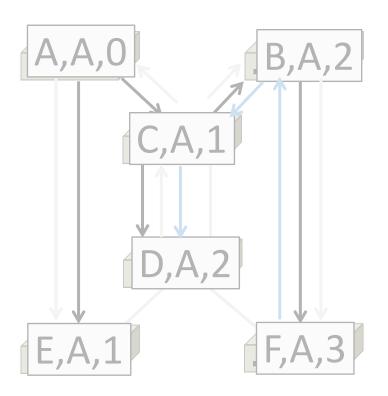

Spanning Tree Example (6)

- Forwarding proceeds as usual on the ST
- Initially D sends to F:
 - D \rightarrow C-left
 - $C \rightarrow A, B$
 - $\bullet A \rightarrow E$
 - $B \rightarrow F$

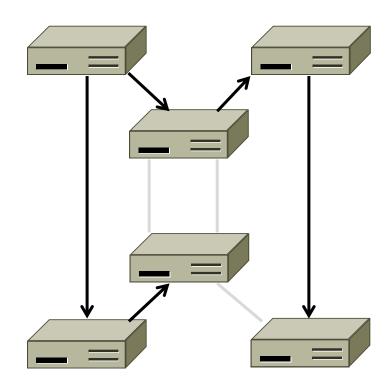

Problems?

- And F sends back to D:
 - $F \rightarrow B$
 - $B \rightarrow C$
 - $\cdot C \rightarrow D$

Challenges with Switching

- Long paths
- Wasted capacity
- Lack of redundancy

Switching vs Routing

- Switches are easier to set up plug and play
 - Routing requires configuration
- Routing scales better
 - Hierarchy, aggregation, subnetting
- Routing uses network resources better

Algorhyme by Radia Perlman

I think that I shall never see A graph more lovely than a tree. A tree whose crucial property Is loop-free connectivity. A tree that must be sure to span So packets can reach every LAN. First, the root must be selected. By ID, it is elected. Least-cost paths from root are traced. In the tree, these paths are placed. A mesh is made by folks like me, Then bridges find a spanning tree.
