Game playing

Chapter 5, Sections 1-5

AIMA Slides @Stuart Russell and Peter Norvig, 1998

Chapter 5, Sections 1-5 1

Outline

- ♦ Perfect play
- ♦ Resource limits
- $\Diamond \quad \alpha \beta \text{ pruning}$
- ♦ Games of chance

AlMA Slides @ Stuart Russell and Peter Norvig, 1998

Chapter 5, Sections 1-5 2

Games vs. search problems

"Unpredictable" opponent \Rightarrow solution is a contingency plan

Time limits \Rightarrow unlikely to find goal, must approximate

Plan of attack:

- algorithm for perfect play (Von Neumann, 1944)
- finite horizon, approximate evaluation (Zuse, 1945; Shannon, 1950; Samuel, 1952-57)
- pruning to reduce costs (McCarthy, 1956)

Types	οf	games
I J P C B	O1	Sames

	deterministic	chance
perfect information	chess, checkers, go, othello	backgammon monopoly
imperfect information		bridge, poker, scrabble nuclear war

Chapter 5, Sections 1-5 4

Minimax

Perfect play for deterministic, perfect-information games

Idea: choose move to position with highest $minimax\ value$ = best achievable payoff against best play

Minimax algorithm

function Minimax-Decision(game) returns an operator

 $\begin{array}{c} \textbf{for each } op \textbf{ in } \text{Operators}[game] \textbf{ do} \\ \text{Value}[op] \leftarrow \text{Minimax-Value}(\text{Apply}(op,game),game) \end{array}$

return the op with the highest Value[op]

 $\mathbf{function} \ \mathbf{Minimax-Value} \big(state, game \big) \ \mathbf{returns} \ \ a \ utility \ value$

if Terminal-Test[game](state) then

return UTILITY [game] (state)
else if MAX is to move in state then
return the highest MINIMAX-VALUE of SUCCESSORS (state)

return the lowest Minimax-Value of Successors(state)

Properties of minimax

Complete??

Optimal??

Time complexity??

Space complexity??

AIMA Slides @Stuart Russell and Peter Norvig, 1998

Chapter 5, Sections 1-5 7

Properties of minimax

Complete?? Yes, if tree is finite (chess has specific rules for this)

Optimal?? Yes, against an optimal opponent. Otherwise??

Time complexity?? $O(b^m)$

Space complexity?? O(bm) (depth-first exploration)

For chess, $b \approx 35$, $m \approx 100$ for "reasonable" games ⇒ exact solution completely infeasible

AlMA Slides @ Stuart Russell and Peter Norvig, 1998

Chapter 5, Sections 1-5 8

Resource limits

Suppose we have 100 seconds, explore 10^4 nodes/second $\Rightarrow \underline{10^6}$ nodes per move

Standard approach:

- cutoff test
 - e.g., depth limit (perhaps add quiescence search)
- ullet evaluation function
 - = estimated desirability of position

AIMA Slides @Stuart Russell and Peter Norvig, 1998

Chapter 5, Sections 1-5 9

Evaluation functions

Black winning

Black to move White slightly better

For chess, typically linear weighted sum of features

EVAL
$$(s) = w_1 f_1(s) + w_2 f_2(s) + \ldots + w_n f_n(s)$$

eg $w_1 = 9$ with

 $f_1(s) =$ (number of white queens) – (number of black queens) etc.

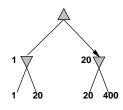

AIMA Slides @ Stuart Russell and Peter Norvig, 1998

Chapter 5, Sections 1-5 10

Digression: Exact values don't matter

MAX MIN

Behaviour is preserved under any $\mathit{monotonic}$ transformation of Eval

Only the order matters:

payoff in deterministic games acts as an $ordinal\ utility$ function

Cutting off search

 $\label{eq:minimax} \mathbf{Minimax} \mathbf{Value} \ \ \textbf{except}$

- 1. TERMINAL? is replaced by CUTOFF?
- 2. UTILITY is replaced by EVAL

Does it work in practice?

$$b^m = 10^6$$
, $b = 35$ \Rightarrow $m = 4$

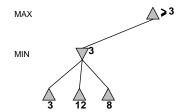

4-ply lookahead is a hopeless chess player!

4-ply \approx human novice

8-ply \approx typical PC, human master

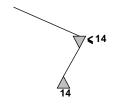

12-ply \approx Deep Blue, Kasparov

α - β pruning example

AlMA Slides @Suar. Runell and Peter Norvig, 1998 Chapter 3, Sections 1-5 13 AlMA Slides @Suar. Runell and Peter Norvig, 1998 Chapter 5, Sections 1-5 14

AIMA Sides @ N uart Russell and Peter Norvig, 1998 Chapter 5, Sections 1-5 15 AIMA Sides @ N uart Russell and Peter Norvig, 1998 Chapter 5, Sections 1-5 16

Properties of α - β

Pruning $does \ not$ affect final result

Good move ordering improves effectiveness of pruning

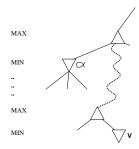

With "perfect ordering," time complexity $= O(b^{m/2})$

 $\Rightarrow doubles \ {\sf depth} \ {\sf of} \ {\sf search}$

⇒ can easily reach depth 8 and play good chess

A simple example of the value of reasoning about which computations are relevant (a form of metareasoning)

Why is it called $\alpha-\beta$?

lpha is the best value (to MAX) found so far off the current path

If V is worse than α , MAX will avoid it \Rightarrow prune that branch

Define β similarly for MIN

AlMA Slides @ Stuart Russell and Peter Norvig, 1998

Chapter 5, Sections 1-5 19

The α - β algorithm

Basically M_{INIMAX} + keep track of α , β + prune

```
function Max-Value(state, game, \alpha, \beta) returns the minimax value of state inputs: state, current state in game game, game description \alpha, the best score for Max along the path to state \beta, the best score for Mix along the path to state if Cutoff-Test(state) then return Eval(state) for each s in Successons(state) do \alpha \leftarrow \text{Max}(\alpha, \text{Min-Value}(s, game, \alpha, \beta)) if \alpha \geq \beta then return \beta end return \alpha

function Min-Value(state, game, \alpha, \beta) returns the minimax value of state if Cutoff-Test(state) then return Eval(state) for each s in Successons(state) do \beta \leftarrow \text{Mix}(\beta, \text{Max-Value}(s, game, \alpha, \beta)) if \beta \leq \alpha then return \alpha end return \beta
```

AIMA Slides @Stuart Russell and Peter Norvig, 1998

Chapter 5, Sections 1-5 20

Deterministic games in practice

Checkers: Chinook ended 40-year-reign of human world champion Marion Tinsley in 1994. Used an endgame database defining perfect play for all positions involving 8 or fewer pieces on the board, a total of 443,748,401,247 positions.

Chess: Deep Blue defeated human world champion Gary Kasparov in a six-game match in 1997. Deep Blue searches 200 million positions per second, uses very sophisticated evaluation, and undisclosed methods for extending some lines of search up to 40 ply.

Othello: human champions refuse to compete against computers, who are too good.

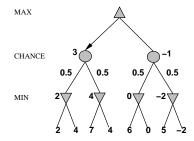

Go: human champions refuse to compete against computers, who are too bad. In go, b>300, so most programs use pattern knowledge bases to suggest plausible moves.

AlMA Slides @ Stuart Russell and Peter Norvig, 1998

Chapter 5, Sections 1-5 21

Nondeterministic games

E..g, in backgammon, the dice rolls determine the legal moves Simplified example with coin-flipping instead of dice-rolling:

AlMA Slides @ Stuart Russell and Peter Norvig, 1998

Chapter 5, Sections 1-5 22

Algorithm for nondeterministic games

 $Expectiminimax \ \ \text{gives perfect play}$

Just like $\mathbf{M}^{\mathrm{INIM}\,\mathrm{AX}}$, except we must also handle chance nodes:

if state is a chance node then
return average of ExpectiMinimax-Value of Successors(state)

A version of α - β pruning is possible but only if the leaf values are bounded. Why??

Nondeterministic games in practice

Dice rolls increase b: 21 possible rolls with 2 dice Backgammon \approx 20 legal moves (can be 6,000 with 1-1 roll)

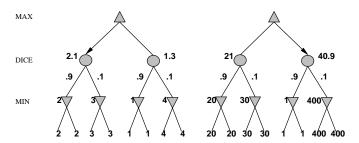

depth
$$4 = 20 \times (21 \times 20)^3 \approx 1.2 \times 10^9$$

As depth increases, probability of reaching a given node shrinks \Rightarrow value of lookahead is diminished

 α - β pruning is much less effective

 $\begin{aligned} TDG_{AMMON} \text{ uses depth-2 search } + \text{very good } Eval\\ \approx \text{world-champion level} \end{aligned}$

Digression: Exact values DO matter

Behaviour is preserved only by $positive\ linear$ transformation of Eval Hence Eval should be proportional to the expected payoff

Summary

Games are fun to work on! (and dangerous)

They illustrate several important points about AI

- $\diamondsuit \ \ \mathsf{perfection} \ \mathsf{is} \ \mathsf{unattainable} \Rightarrow \mathsf{must} \ \mathsf{approximate}$
- $\diamondsuit \;$ good idea to think about what to think about
- \diamondsuit uncertainty constrains the assignment of values to states

Games are to AI as grand prix racing is to automobile design
