

# CSE 473: Artificial Intelligence

## Constraint Satisfaction

Daniel Weld

Slides adapted from Dan Klein, Stuart Russell, Andrew Moore & Luke Zettlemoyer

## Space of Search Strategies

- **Blind Search**
  - DFS, BFS, IDS
- **Informed Search**
  - Systematic: Uniform cost, greedy, A\*, IDA\*
  - Stochastic: Hill climbing w/ random walk & restarts
- **Constraint Satisfaction**
  - Backtracking=DFS, FC, k-consistency
- **Adversary Search**

2

## Recap: Search Problem

- **States**
  - configurations of the world
- **Successor function:**
  - function from states to lists of triples (state, action, cost)
- **Start state**
- **Goal test**

## Recap: Constraint Satisfaction

- Kind of **search** in which
  - States are **factored** into sets of variables
  - Search = assigning values to these variables
  - Goal test is encoded with constraints
    - → Gives **structure** to search space
    - Exploration of one part informs others
- **Special techniques add speed**
  - Propagation
  - Variable ordering
  - Preprocessing

4

## Constraint Satisfaction Problems

- Subset of search problems
- State is defined by
  - Variables  $X_i$  with values from a
  - Domain  $D$  (often  $D$  depends on  $i$ )
- Goal test is a **set of constraints**

## Real-World CSPs

- Assignment problems: e.g., who teaches what class
- Timetabling problems: e.g., which class is offered when and where?
- Hardware configuration
- Gate assignment in airports
- Transportation scheduling
- Factory scheduling
- Fault diagnosis
- ... lots more!
- Many real-world problems involve real-valued variables...

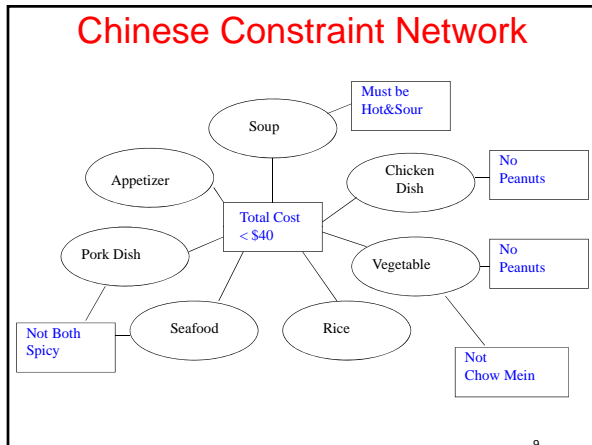

## Chinese Food, Family Style

- Suppose  $k$  people...
- Variables & Domains?
- Constraints?

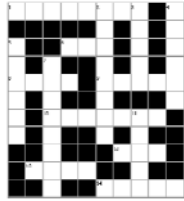

## Factoring States

- Model state's (independent) parts, e.g.
  - Suppose every meal for  $n$  people
  - Has  $n$  dishes plus soup
- Soup =
- Meal 1 =
- Meal 2 =
- ...
- Meal  $n$  =

## Crossword Puzzle

- Variables & domains?
- Constraints?

**ACROSS**

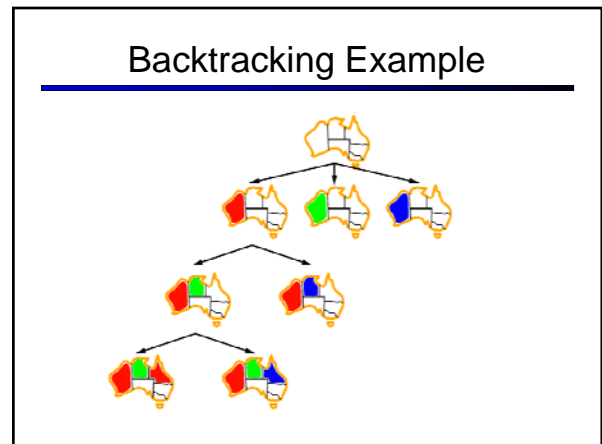

1. Matt Johnson's cartoon.
6. David Allen's week life management system (abbr.)
8. The program, SuperNova, can filter out certain effects of Galia, OFM software, and Nigerian bank accounts.
9. Popular AT&T film name.
10. The author about Stone

**DOWN**

2. Upper source sound editor.
3. David Robinson 2D.
4. Popular online book www.crowdsourcing
5. Business follow.
7. Mark Tomber's column.
11. First name of the who was on Soapnet and Who Wants To Be A Millionaire.

## Standard Search Formulation

- States are defined by the values assigned so far
- Initial state: the empty assignment, {}
- Successor function:
  - assign value to an unassigned variable
- Goal test:
  - the current assignment is complete &
  - satisfies all constraints

## Backtracking Search

---

- **Note 1:** Only consider a single variable at each point
  - Variable assignments are commutative, so **fix ordering of variables**  
 I.e., [WA = red then NT = blue] same as  
 [NT = blue then WA = red]
  - What is **branching factor** of this search?

## Backtracking Search

---

**Note 2:** Only allow legal assignments at each point

- I.e. Ignore values which conflict previous assignments
- Might need some computation to eliminate such conflicts
- "Incremental goal test"

## "Backtracking Search"

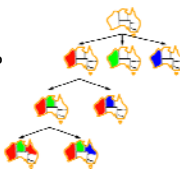

---

Depth-first search for CSPs with these two ideas

- One variable at a time, fixed order
- Only trying consistent assignments

Is called "Backtracking Search"

- Basic uninformed algorithm for CSP
- Can solve n-queens for n H 25

## Backtracking Search

---

```

function BACKTRACKING-SEARCH(csp) returns solution/failure
  return RECURSIVE-BACKTRACKING({}, csp)
function RECURSIVE-BACKTRACKING(assignment, csp) returns soln/failure
  if assignment is complete then return assignment
  var ← SELECT-UNASSIGNED-VARIABLE(VARIABLES[csp], assignment, csp)
  for each value in ORDER-DOMAIN-VALUES(var, assignment, csp) do
    if value is consistent with assignment given CONSTRAINTS[csp] then
      add {var = value} to assignment
      result ← RECURSIVE-BACKTRACKING(assignment, csp)
      if result ≠ failure then return result
      remove {var = value} from assignment
  return failure
    
```

- What are the choice points?

## Improving Backtracking

---

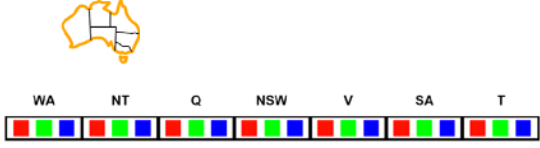

- General-purpose ideas give huge gains in speed
- **Ordering:**
  - Which variable should be assigned next?
  - In what order should its values be tried?
- **Filtering:** Can we detect inevitable failure early?
- **Structure:** Can we exploit the problem structure?

## Forward Checking

---

- Idea: Keep track of remaining legal values for unassigned variables (using immediate constraints)
- Idea: Terminate when any variable has no legal values

### Forward Checking

	Q <sub>A</sub>	Q <sub>B</sub>	Q <sub>C</sub>	Q <sub>D</sub>
Row 1				
Row 2				
Row 3				
Row 4				

1	1	1	1
2	2	2	2
3	3	3	3
4	4	4	4

Possible values

21

### Forward Checking

27

### Are We Done?

28

### Constraint Propagation

WA	NT	Q	NSW	V	SA	T
Red, Green, Blue	Red, Green, Blue	Red, Green, Blue	Red, Green, Blue	Red, Green, Blue	Red, Green, Blue	Red, Green, Blue
Red	Green	Blue	Red, Green, Blue	Red, Green, Blue	Red, Green, Blue	Red, Green, Blue
Red	Green	Blue	Red, Green, Blue	Red, Green, Blue	Red, Green, Blue	Red, Green, Blue

- Forward checking propagates information from assigned to adjacent unassigned variables, but doesn't detect more distant failures:
- NT and SA cannot both be blue!
- Why didn't we detect this yet?
- Constraint propagation repeatedly enforces constraints (locally)

### Arc Consistency

WA	NT	Q	NSW	V	SA	T
Red	Blue	Green	Red, Green, Blue	Red, Green, Blue	Red, Green, Blue	Red, Green, Blue
Red	Blue	Green	Red, Green, Blue	Red, Green, Blue	Red, Green, Blue	Red, Green, Blue
Red	Blue	Green	Red, Green, Blue	Red, Green, Blue	Red, Green, Blue	Red, Green, Blue

- Simplest form of propagation makes each arc consistent
  - $X \leftrightarrow Y$  is consistent iff for every value  $x$  there is some allowed  $y$
- If  $X$  loses a value, neighbors of  $X$  need to be rechecked!
- Arc consistency detects failure earlier than forward checking
- What's the downside of arc consistency?
- Can be run as a preprocessor or after each assignment

### Arc Consistency

```

function AC-3(esp) returns the CSP, possibly with reduced domains
inputs: esp, a binary CSP with variables  $\{X_1, X_2, \dots, X_n\}$ 
local variables: queue, a queue of arcs, initially all the arcs in esp
while queue is not empty do
   $(X_i, X_j) \leftarrow \text{REMOVE-FIRST}(\textit{queue})$ 
  if REMOVE-INCONSISTENT-VALUES( $X_i, X_j$ ) then
    for each  $X_k$  in NEIGHBORS[ $X_i$ ] do
      add  $(X_k, X_i)$  to queue

function REMOVE-INCONSISTENT-VALUES( $X_i, X_j$ ) returns true iff succeeds
removed ← false
for each  $x$  in DOMAIN[ $X_i$ ] do
  if no value  $y$  in DOMAIN[ $X_j$ ] allows  $(x, y)$  to satisfy the constraint  $X_i \leftrightarrow X_j$ 
  then delete  $x$  from DOMAIN[ $X_i$ ]; removed ← true
return removed
    
```

- Runtime:  $O(n^2d^3)$ , can be reduced to  $O(n^2d^2)$
- ... but detecting all possible future problems is NP-hard – why? [demo: arc consistency animation]

### Limitations of Arc Consistency

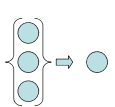

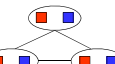

- After running arc consistency:
  - Can have one solution left
  - Can have multiple solutions left
  - Can have no solutions left (and not know it)

What went wrong here?

### K-Consistency\*

---

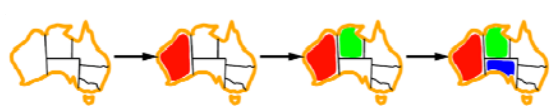

- Increasing degrees of consistency
  - 1-Consistency (Node Consistency): Each single node's domain has a value which meets that node's unary constraints
  - 2-Consistency (Arc Consistency): For each pair of nodes, any consistent assignment to one can be extended to the other
  - K-Consistency: For each k nodes, any consistent assignment to k-1 can be extended to the k<sup>th</sup> node.
- Higher k more expensive to compute
- (You need to know the k=2 algorithm)

### Ordering: Minimum Remaining Values

---

- Minimum remaining values (MRV):
  - Choose the variable with the fewest legal values

- Why min rather than max?
- Also called "most constrained variable"
- "Fail-fast" ordering

### Ordering: Degree Heuristic

---

- Tie-breaker among MRV variables
- Degree heuristic:
  - Choose the variable participating in the most constraints on remaining variables

- Why most rather than fewest constraints?

### Ordering: Least Constraining Value

---

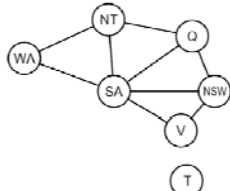

- Given a choice of variable:
  - Choose the *least constraining value*
  - The one that rules out the fewest values in the remaining variables
  - Note that it may take some computation to determine this!
- Why least rather than most?
- Combining these heuristics makes 1000 queens feasible

### Problem Structure

---

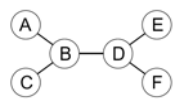

- Tasmania and mainland are independent subproblems
- Identifiable as connected components of constraint graph
- Suppose each subproblem has c variables out of n total
- Worst-case solution cost is  $O((n/c)(d^c))$ , linear in n
  - E.g., n = 80, d = 2, c = 20
  - $2^{80}$  = 4 billion years at 10 million nodes/sec
  - $(4)(2^{20})$  = 0.4 seconds at 10 million nodes/sec

### Tree-Structured CSPs

---

- Choose a variable as root, order variables from root to leaves such that every node's parent precedes it in the ordering

- For  $i = n : 2$ , apply RemoveInconsistent(Parent( $X_i$ ),  $X_i$ )
- For  $i = 1 : n$ , assign  $X_i$  consistently with Parent( $X_i$ )
- Runtime:  $O(n d^2)$

### Tree-Structured CSPs

---

- Theorem: if the constraint graph has no loops, the CSP can be solved in  $O(n d^2)$  time!
  - Compare to general CSPs, where worst-case time is  $O(d^n)$
- This property also applies to logical and probabilistic reasoning: an important example of the relation between syntactic restrictions and the complexity of reasoning.

### Nearly Tree-Structured CSPs

---

- Conditioning: instantiate a variable, prune its neighbors' domains
- Cutset conditioning: instantiate (in all ways) a set of variables such that the remaining constraint graph is a tree
- Cutset size  $c$  gives runtime  $O((d^c)(n-c)d^2)$ , very fast for small  $c$

### Iterative Algorithms for CSPs

---

- Greedy and local methods typically work with "complete" states, i.e., all variables assigned
- To apply to CSPs:
  - Allow states with unsatisfied constraints
  - Operators *reassign* variable values
- Variable selection: randomly select any conflicted variable
- Value selection by min-conflicts heuristic:
  - Choose value that violates the fewest constraints
  - I.e., hill climb with  $h(n)$  = total number of violated constraints

### Example: 4-Queens

---

- States: 4 queens in 4 columns ( $4^4 = 256$  states)
- Operators: move queen in column
- Goal test: no attacks
- Evaluation:  $h(n)$  = number of attacks

### Performance of Min-Conflicts

---

- Given random initial state, can solve  $n$ -queens in almost constant time for arbitrary  $n$  with high probability (e.g.,  $n = 10,000,000$ )
- The same appears to be true for any randomly-generated CSP except in a narrow range of the ratio
 
$$R = \frac{\text{number of constraints}}{\text{number of variables}}$$

### Summary

- CSPs are a special kind of search problem:
  - States defined by values (domains) of a fixed set of variables
  - Goal test defined by constraints on variable values
- Backtracking = DFS - one legal variable assigned per node
- Variable ordering and value selection heuristics help
- Forward checking prevents assignments that fail later
- Constraint propagation (e.g., arc consistency)
  - does additional work to constrain values and detect inconsistencies
- Constraint graph representation
  - Allows analysis of problem structure
- Tree-structured CSPs can be solved in linear time
- Iterative min-conflicts is usually effective in practice
  - Local (stochastic) search
