

 Using a feature representation, we can write a q function (or value function) for any state using a few weights:

 $V(s) = w_1 f_1(s) + w_2 f_2(s) + \ldots + w_n f_n(s)$ 

 $Q(s,a) = w_1 f_1(s,a) + w_2 f_2(s,a) + \ldots + w_n f_n(s,a)$ 

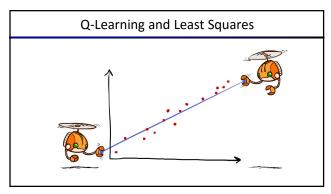

Advantage: our experience is summed up in a few powerful numbers

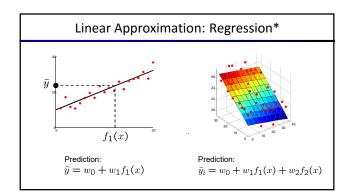

Disadvantage: states may share features but actually be very different in value!

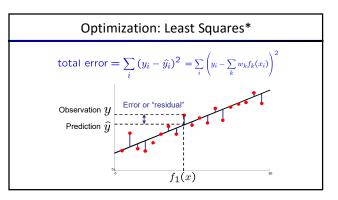

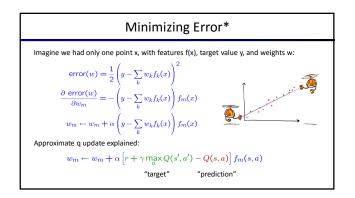

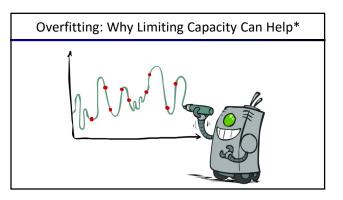

## **Policy Search**

- Simplest policy search:
- Start with an initial linear value function or Q-function
- Nudge each feature weight up and down and see if your policy is better than before
- Problems:
  - How do we tell the policy got better?
  - Need to run many sample episodes!
  - If there are a lot of features, this can be impractical
- Better methods exploit lookahead structure, sample wisely, change multiple parameters...
