

# CSE 473: Artificial Intelligence

## Particle Filters

Steve Tanimoto --- University of Washington

[Most slides were created by Dan Klein and Pieter Abbeel for CS188 intro to AI at UC Berkeley. All CS188 materials are available at <http://ai.berkeley.edu>.]

## Particle Filtering

- Filtering: approximate solution
- Sometimes  $|X|$  is too big to use exact inference
  - $|X|$  may be too big to even store  $B(X)$
  - E.g.  $X$  is continuous
  - $|X|^2$  may be too big to do updates
- Solution: approximate inference
  - Track samples of  $X$ , not all values
  - Samples are called particles
  - Time per step is linear in the number of samples
  - But: number needed may be large
  - In memory: list of particles, not states
- This is how robot localization works in practice

## Representation: Particles

- Our representation of  $P(X)$  is now a list of  $N$  particles (samples)
  - Generally,  $N \ll |X|$
  - Storing map from  $X$  to counts would defeat the point
- $P(x)$  approximated by number of particles with value  $x$ 
  - So, many  $x$  may have  $P(x) = 0!$
  - More particles, more accuracy
- For now, all particles have a weight of 1

## Particle Filtering: Elapse Time

- Each particle is moved by sampling its next position from the transition model
  - This is like prior sampling – samples' frequencies reflect the transition probabilities
  - Here, most samples move clockwise, but some move in another direction or stay in place
- This captures the passage of time
  - If enough samples, close to exact values before and after (consistent)

## Particle Filtering: Observe

- Slightly trickier:
  - Don't sample observation, fix it
  - Similar to likelihood weighting, downweight samples based on the evidence
- As before, the probabilities don't sum to one, since all have been downweighted (in fact they now sum to  $(N \text{ times})$  an approximation of  $P(e)$ )

$$w(x) = P(e|x)$$

$$B(X) \propto P(e|X)B'(X)$$

## Particle Filtering: Resample

- Rather than tracking weighted samples, we resample
- $N$  times, we choose from our weighted sample distribution (i.e. draw with replacement)
- This is equivalent to renormalizing the distribution
- Now the update is complete for this time step, continue with the next one

## Recap: Particle Filtering

- Particles: track samples of states rather than an explicit distribution

[Demo: ghostbusters particle filtering (L15D3.4.5)]

## Video of Demo – Moderate Number of Particles

## Video of Demo – One Particle

## Video of Demo – Huge Number of Particles

## Dynamic Bayes Nets

## Dynamic Bayes Nets (DBNs)

- We want to track multiple variables over time, using multiple sources of evidence
- Idea: Repeat a fixed Bayes net structure at each time
- Variables from time  $t$  can condition on those from  $t-1$

- Dynamic Bayes nets are a generalization of HMMs

[Demo: pacman sonar ghost DBN model (L15D6)]

## DBN Particle Filters

- A particle is a complete sample for a time step
- **Initialize:** Generate prior samples for the  $t=1$  Bayes net
  - Example particle:  $\mathbf{G}_1^a = (3,3)$   $\mathbf{G}_1^b = (5,3)$
- **Elastse time:** Sample a successor for each particle
  - Example successor:  $\mathbf{G}_2^a = (2,3)$   $\mathbf{G}_2^b = (6,3)$
- **Observe:** Weight each *entire* sample by the likelihood of the evidence conditioned on the sample
  - Likelihood:  $P(\mathbf{E}_1^a | \mathbf{G}_1^a) * P(\mathbf{E}_1^b | \mathbf{G}_1^b)$
- **Resample:** Select prior samples (tuples of values) in proportion to their likelihood
