

# CSE 473: Artificial Intelligence

## Bayes' Nets

Dieter Fox

[Most slides were created by Dan Klein and Pieter Abbeel for CS188 intro to AI at UC Berkeley. All CS188 materials are available at <http://ai.berkeley.edu>.]

## Bayes' Nets: Big Picture

- Two problems with using full joint distribution tables as our probabilistic models:
  - Unless there are only a few variables, the joint is WAY too big to represent explicitly
  - Hard to learn (estimate) anything empirically about more than a few variables at a time
- Bayes' nets: a technique for describing complex joint distributions (models) using simple, local distributions (conditional probabilities)
  - More properly called **graphical models**
  - We describe how variables locally interact
  - Local interactions chain together to give global, indirect interactions
  - For about 10 min, we'll be vague about how these interactions are specified

## Graphical Model Notation

- Nodes: variables (with domains)
  - Can be assigned (observed) or unassigned (unobserved)
- Arcs: interactions
  - Similar to CSP constraints
  - Indicate "direct influence" between variables
  - Formally: encode conditional independence (more later)
- For now: imagine that arrows mean direct causation (in general, they don't!)

## Example: Coin Flips

- N independent coin flips

- No interactions between variables: **absolute independence**

## Example: Traffic

- Variables:
  - R: It rains
  - T: There is traffic

- Model 1: independence

- Model 2: rain causes traffic

- Why is an agent using model 2 better?

## Example: Traffic II

- Let's build a causal graphical model!

- Variables
  - T: Traffic
  - R: It rains
  - L: Low pressure
  - D: Roof drips
  - B: Ballgame
  - C: Cavity

## Example: Alarm Network

### Variables

- B: Burglary
- A: Alarm goes off
- M: Mary calls
- J: John calls
- E: Earthquake!

## Bayes' Net Semantics

## Bayes' Net Semantics

- A set of nodes, one per variable  $X$
- A directed, acyclic graph
- A conditional distribution for each node
  - A collection of distributions over  $X$ , one for each combination of parents' values
- CPT: conditional probability table
- Description of a noisy "causal" process

*A Bayes net = Topology (graph) + Local Conditional Probabilities*

## Probabilities in BNs

- Bayes' nets **implicitly** encode joint distributions
- As a product of local conditional distributions
- To see what probability a BN gives to a full assignment, multiply all the relevant conditionals together:

$$P(x_1, x_2, \dots, x_n) = \prod_{i=1}^n P(x_i | \text{parents}(X_i))$$

- Example:

$$P(+cavity, +catch, -toothache)$$

## Probabilities in BNs

- Why are we guaranteed that setting

$$P(x_1, x_2, \dots, x_n) = \prod_{i=1}^n P(x_i | \text{parents}(X_i))$$

results in a proper joint distribution?

- Chain rule (valid for all distributions):  $P(x_1, x_2, \dots, x_n) = \prod_{i=1}^n P(x_i | x_1 \dots x_{i-1})$
  - Assume conditional independences:  $P(x_i | x_1, \dots, x_{i-1}) = P(x_i | \text{parents}(X_i))$
- Consequence:  $P(x_1, x_2, \dots, x_n) = \prod_{i=1}^n P(x_i | \text{parents}(X_i))$

- Not every BN can represent every joint distribution
  - The topology enforces certain conditional independencies

## Example: Coin Flips

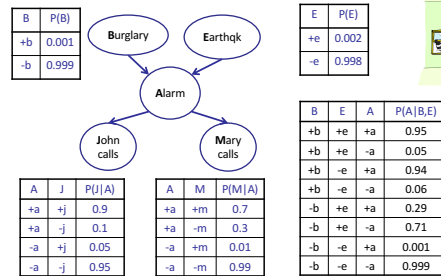

$$P(h, h, t, h) =$$

*Only distributions whose variables are absolutely independent can be represented by a Bayes' net with no arcs.*

### Example: Traffic

### Example: Alarm Network

### Example: Traffic

- Causal direction

### Example: Reverse Traffic

- Reverse causality?

### Causality?

- When Bayes' nets reflect the true causal patterns:
  - Often simpler (nodes have fewer parents)
  - Often easier to think about
  - Often easier to elicit from experts

- BNs need not actually be causal
  - Sometimes no causal net exists over the domain (especially if variables are missing)
  - E.g. consider the variables *Traffic* and *Drips*
  - End up with arrows that reflect correlation, not causation

- What do the arrows really mean?
  - Topology may happen to encode causal structure
  - Topology really encodes conditional independence

$$P(x_i|x_1, \dots, x_{i-1}) = P(x_i|\text{parents}(X_i))$$

### Size of a Bayes' Net

- How big is a joint distribution over  $N$  Boolean variables?
  - Both give you the power to calculate  $2^N$
  - BNs: Huge space savings!
- How big is an  $N$ -node net if nodes have up to  $k$  parents?
  - Also easier to elicit local CPTs
  - Also faster to answer queries (coming)

## Bayes' Nets

- So far: how a Bayes' net encodes a joint distribution
- Next: how to answer queries about that distribution
  - Today:
    - First assembled BNs using an intuitive notion of conditional independence as causality
    - Then saw that key property is conditional independence
  - Main goal: answer queries about conditional independence and influence
- After that: how to answer numerical queries (inference)
