

AC-3 algorithm for Arc Consistency function AC-3{ csp} returns the CSP, possibly with reduced domains inputs: csp, a binary CSP with variables $\{X_1, X_2, \dots, X_s\}$ local variables: $\{x_1, X_2, \dots, X_s\}$ local variables: $\{x_1, X_2, \dots, X_s\}$ local variables: $\{w_1, w_2, \dots, w_s\}$ returns true iff succeeds removed—plase for each x in Domain[X_1] allows $\{x_1, y_2, \dots, y_s\}$ returns true iff succeeds removed—plase for each x in Domain[X_1] allows $\{x_1, y_2, \dots, y_s\}$ then delete x from Domain[X_1] allows $\{x_1, y_2, \dots, y_s\}$ then delete x from Domain[X_1] allows $\{x_1, y_2, \dots, y_s\}$ then delete x from Domain[X_1]: removed—true return removed Runtime: $\{x_1, \dots, x_s\}$ and $\{x_1, \dots, x_s\}$ local variables: $\{x_1, \dots, x_s\}$ returns true iff succeeds removed—true return $\{x_1, \dots, x_s\}$ local variables: $\{x_1, \dots, x_s\}$ local variables: $\{x_1, \dots, x_s\}$ returns true iff succeeds removed—true iff succeeds removed if succeeds

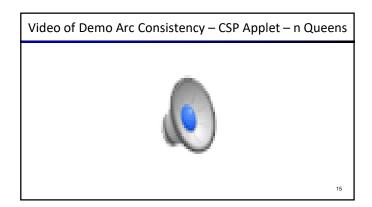

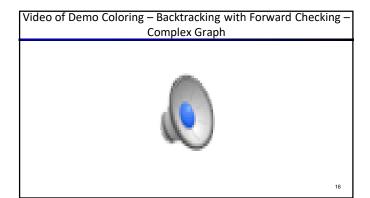

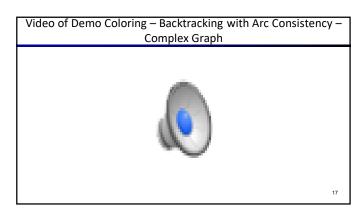

Strong K-Consistency

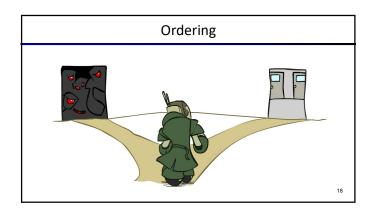

- Strong k-consistency: also k-1, k-2, ... 1 consistent
- Claim: strong n-consistency means we can solve without backtracking!
- Why?
 - Choose any assignment to any variable
 - · Choose a new variable
 - By 2-consistency, there is a choice consistent with the first
 - Choose a new variable
 - By 3-consistency, there is a choice consistent with the first 2
 - ...
- Lots of middle ground between arc consistency and n-consistency! (e.g. k=3, called path consistency)

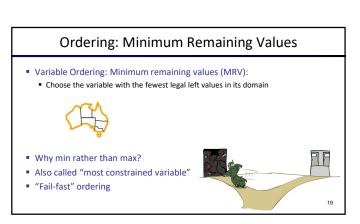

14

Ordering: Maximum Degree

- Tie-breaker among MRV variables
 - What is the very first state to color? (All have 3 values remaining.)
- Maximum degree heuristic:
 - Choose the variable participating in the most constraints on remaining variables

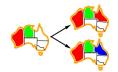

Why most rather than fewest constraints?

20

Ordering: Least Constraining Value

- Value Ordering: Least Constraining Value
 - Given a choice of variable, choose the least constraining value
 - I.e., the one that rules out the fewest values in the remaining variables
 - Note that it may take some computation to determine this! (E.g., rerunning filtering)
- Why least rather than most?
- Combining these ordering ideas makes 1000 queens feasible

Rationale for MRV, MD, LCV

- We want to enter the most promising branch, but we also want to detect failure quickly
- MRV+MD:
 - Choose the variable that is most likely to cause failure
 - It must be assigned at some point, so if it is doomed to fail, better to find out soon
- LCV:
 - We hope our early value choices do not doom us to failure
 - Choose the value that is most likely to succeed

Structure 23

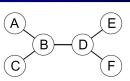

Problem Structure

- - · Example: Tasmania and mainland do not interact
- Independent subproblems are identifiable as connected components of constraint graph
- Suppose a graph of n variables can be broken into subproblems of only c variables:

 Worst-case solution cost is O((n/c)(d')), linear in n

- E.g., n = 80, d = 2, c = 20
 280 = 4 billion years at 10 million nodes/sec
 (4)(2²⁰) = 0.4 seconds at 10 million nodes/sec

Tree-Structured CSPs

- Theorem: if the constraint graph has no loops, the CSP can be solved in O(n d²) time
- This property also applies to probabilistic reasoning (later): an example of the relation between syntactic restrictions and the complexity of reasoning

Tree-Structured CSPs

- Algorithm for tree-structured CSPs:
 - Order: Choose a root variable, order variables so that parents precede children

- A-B-C D-E F
- Remove backward: For i = n : 2, apply RemoveInconsistent(Parent(X_i),X_i)
- Assign forward: For i = 1 : n, assign X_i consistently with Parent(X_i)
- Runtime: O(n d²) (why?)

Tree-Structured CSPs

- Claim 1: After backward pass, all root-to-leaf arcs are consistent
- Proof: Each X

 Y was made consistent at one point and Y's domain could not have been reduced thereafter (because Y's children were processed before Y)

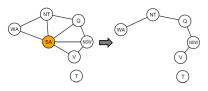

- Claim 2: If root-to-leaf arcs are consistent, forward assignment will not backtrack
- Proof: Induction on position
- Why doesn't this algorithm work with cycles in the constraint graph?
- Note: we'll see this basic idea again with Bayes' nets

28

Improving Structure

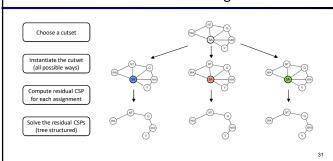

Nearly Tree-Structured CSPs

- Conditioning: instantiate a variable, prune its neighbors' domains
- Cutset conditioning: instantiate (in all ways) a set of variables such that the remaining constraint graph is a tree
- Cutset size c gives runtime O((dc) (n-c) d2), very fast for small c
