Review and Outline

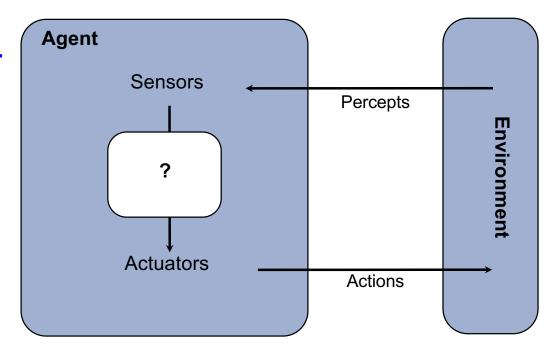

Adversarial Games

- Minimax search
- α-β search
- Evaluation functions
- Multi-player, non-0-sum
- Stochastic Games
 - Expectimax
 - Markov Decision Processes
 - Reinforcement Learning

Agents vs. Environment

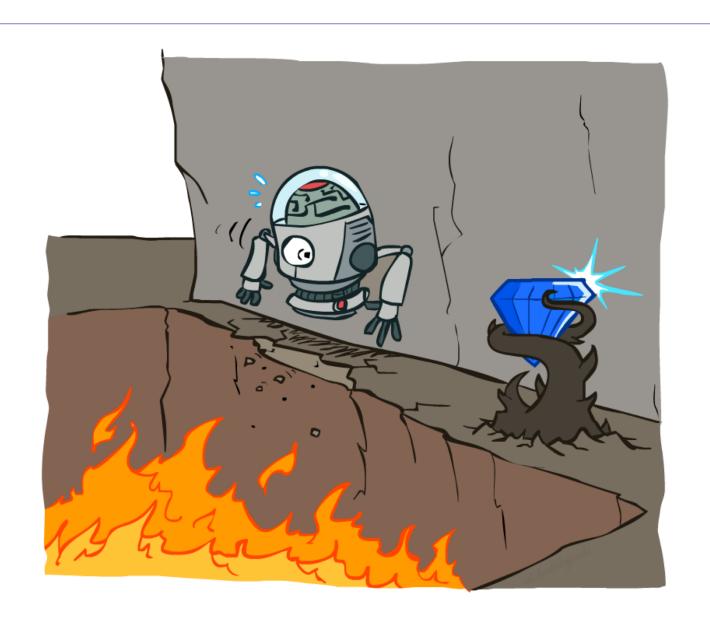

- An agent is an entity that perceives and acts.
- A rational agent selects actions that maximize its utility function.

Deterministic vs. stochastic

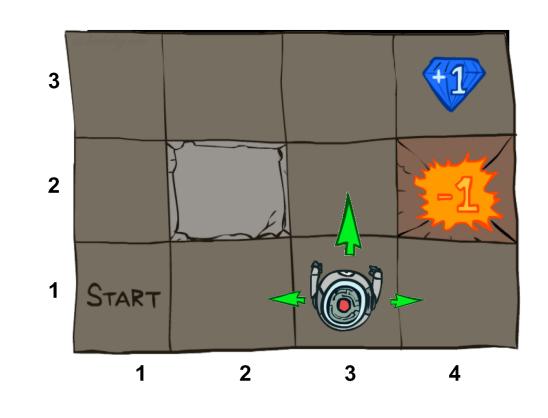

Fully observable vs. partially observable

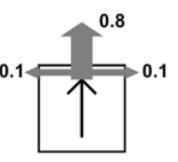

Non-Deterministic Search

Example: Grid World

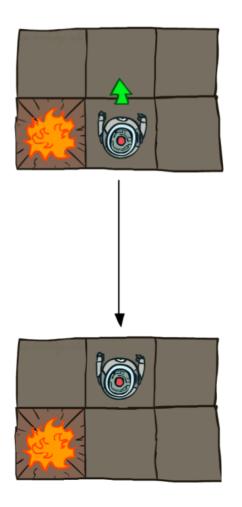

- A maze-like problem
 - The agent lives in a grid
 - Walls block the agent's path
- Noisy movement: actions do not always go as planned
 - 80% of the time, the action North takes the agent North (if there is no wall there)
 - 10% of the time, North takes the agent West; 10% East
 - If there is a wall in the direction the agent would have been taken, the agent stays put
- The agent receives rewards each time step
 - Small "living" reward each step (can be negative)
 - Big rewards come at the end (good or bad)
- Goal: maximize sum of rewards

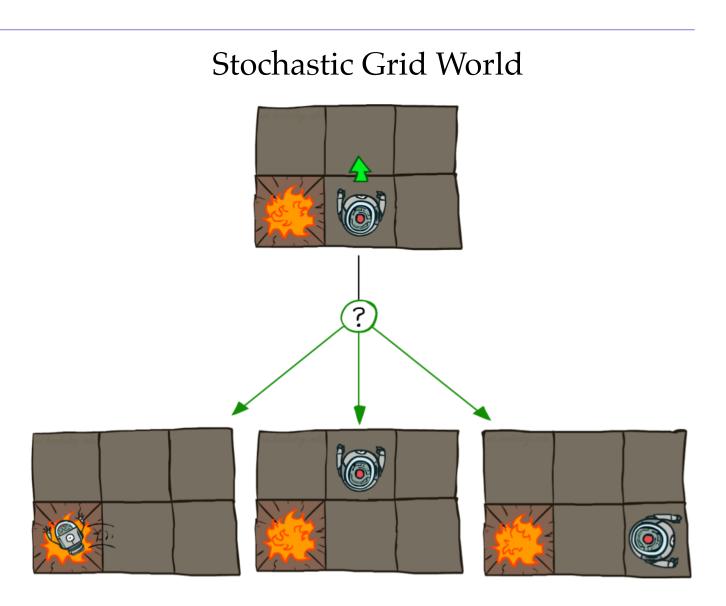

Grid World Actions

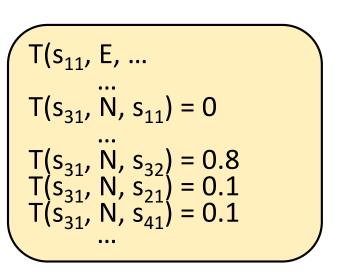

Deterministic Grid World

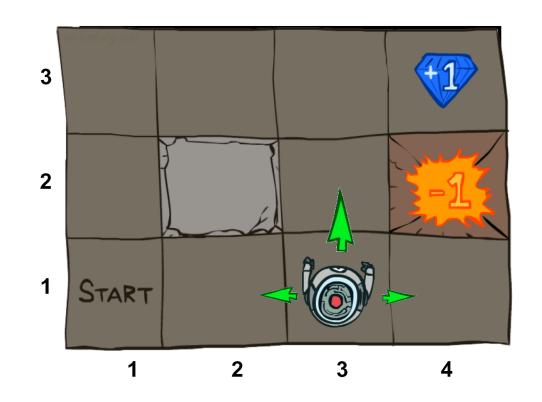

Markov Decision Processes

- An MDP is defined by:
 - \circ A set of states $s \in S$
 - \circ A set of actions $a \in A$
 - A transition function T(s, a, s')
 - o Probability that a from s leads to s', i.e., $P(s' \mid s, a)$
 - Also called the model or the dynamics

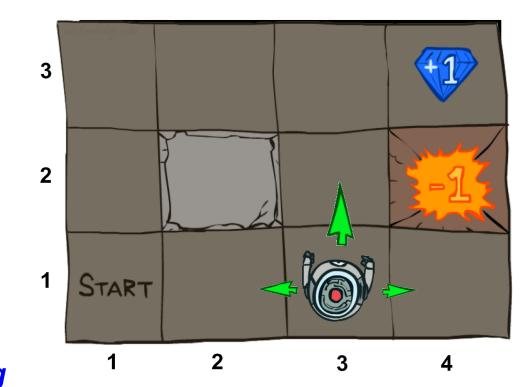

T is a Big Table! 11 X 4 x 11 = 484 entries

For now, we give this as input to the agent

Markov Decision Processes

- An MDP is defined by:
 - \circ A set of states $s \in S$
 - \circ A set of actions $a \in A$
 - A transition function T(s, a, s')
 - o Probability that a from s leads to s', i.e., $P(s' \mid s, a)$
 - Also called the model or the dynamics
 - A reward function R(s, a, s')
 - Sometimes just R(s) or R(s')

$R(s_{32}, N, s_{33}) = -0.01$

$$R(s_{32}, N, s_{42}) = -1.01$$

$$R(s_{33}, E, s_{43}) = 0.99$$

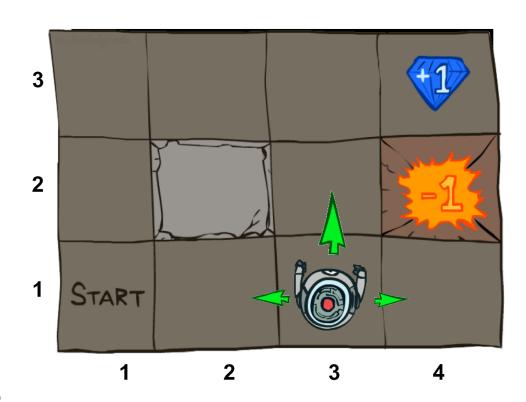

Cost of breathing

R is also a Big Table!

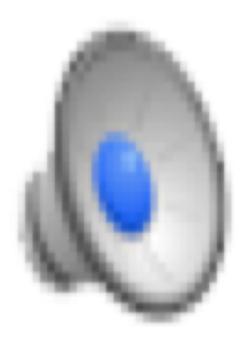

For now, we also give this to the agent

Markov Decision Processes

- An MDP is defined by:
 - \circ A set of states $s \in S$
 - \circ A set of actions $a \in A$
 - A transition function T(s, a, s')
 - o Probability that a from s leads to s', i.e., $P(s' \mid s, a)$
 - Also called the model or the dynamics
 - A reward function R(s, a, s')
 - Sometimes just R(s) or R(s')
 - o A start state
 - Maybe a terminal state
- MDPs are non-deterministic search problems
 - o One way to solve them is with expectimax search
 - We'll have a new tool soon

Video of Demo Gridworld Manual Intro

What is Markov about MDPs?

- "Markov" generally means that given the present state, the future and the past are independent
- For Markov decision processes, "Markov" means action outcomes depend only on the current state

$$P(S_{t+1} = s' | S_t = s_t, A_t = a_t, S_{t-1} = s_{t-1}, A_{t-1}, \dots S_0 = s_0)$$

$$P(S_{t+1} = s' | S_t = s_t, A_t = a_t)$$

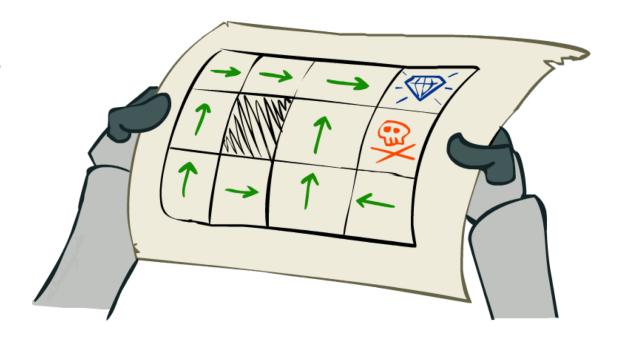

• This is just like search, where the successor function could only depend on the current state (not the history)

Andrey Markov (1856-1922)

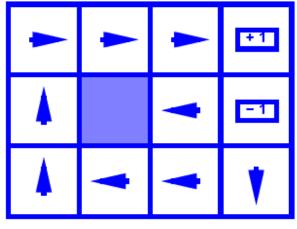

Policies

- In deterministic single-agent search problems, we wanted an optimal plan, or sequence of actions, from start to a goal
- For MDPs, we want an optimal policy $\pi^*: S \to A$
 - o A policy π gives an action for each state
 - An optimal policy is one that maximizes expected utility if followed
 - An explicit policy defines a reflex agent

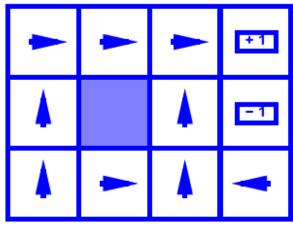

Optimal policy when R(s, a, s') = -0.03 for all non-terminals s

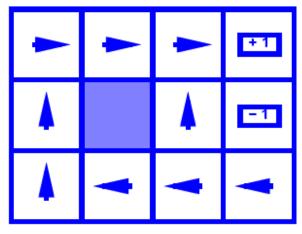

Optimal Policies

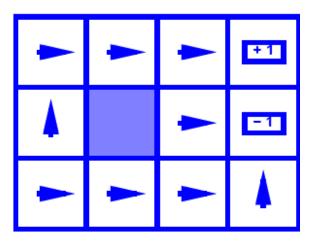

$$R(s) = -0.4$$

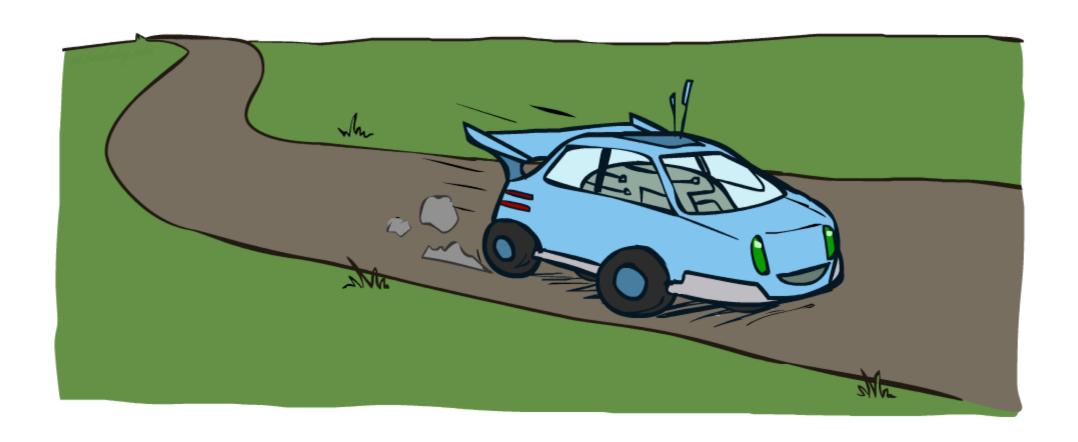

$$R(s) = -0.03$$

R(s) = -2.0

Example: Racing

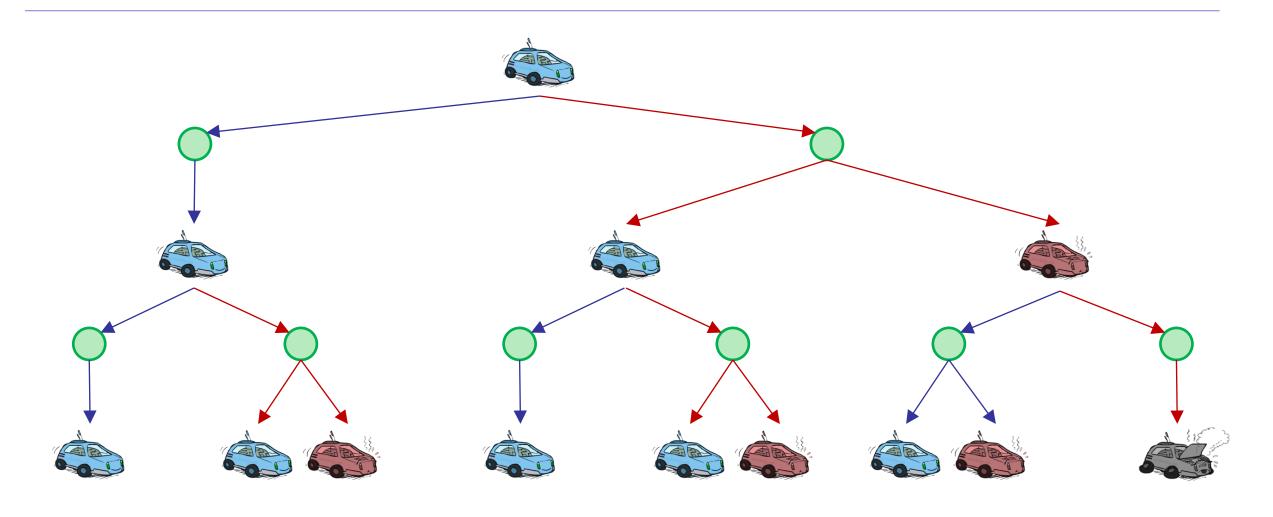

Example: Racing

A robot car wants to travel far, quickly

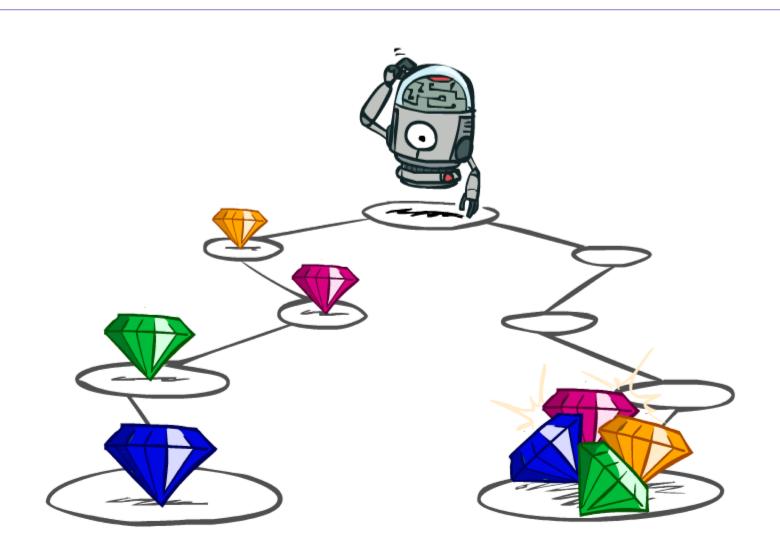

Three states: Cool, Warm, Overheated

Two actions: *Slow*, *Fast* 0.5 +1 Going faster gets double reward 1.0 Fast Slow -10 +1 0.5 Warm Slow 0.5 +2 Fast 0.5 Overheated 1.0

Racing Search Tree

Utilities of Sequences

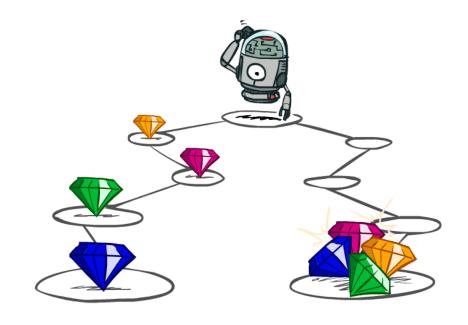

Utilities of Sequences

What preferences should an agent have over reward sequences?

More or less? [1, 2, 2] or [2, 3, 4]

Now or later? [0, 0, 1] or [1, 0, 0]

Discounting

- It's reasonable to maximize the sum of rewards
- It's also reasonable to prefer rewards now to rewards later
- One solution: values of rewards decay exponentially

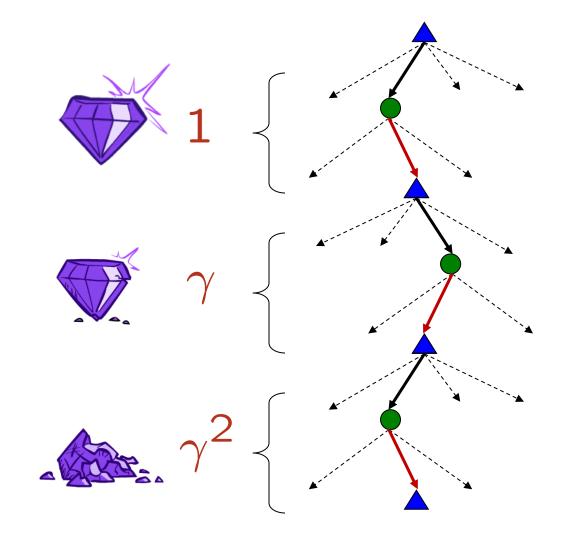

Discounting

o How to discount?

Each time we descend a level,
 we multiply in the discount once

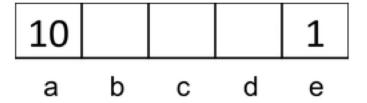

o Why discount?

- Think of it as a gamma chance of ending the process at every step
- Also helps our algorithms converge
- Example: discount of 0.5
 - \circ U([1,2,3]) = 1*1 + 0.5*2 + 0.25*3
 - \circ U([1,2,3]) < U([3,2,1])

Quiz: Discounting

o Given:

- o Actions: East, West, and Exit (only available in exit states a, e)
- o Transitions: deterministic

• Quiz 1: For $\gamma = 1$, what is the optimal policy?

• Quiz 2: For $\gamma = 0.1$, what is the optimal policy?

Quiz 3: For which γ are West and East equally good when in state d?

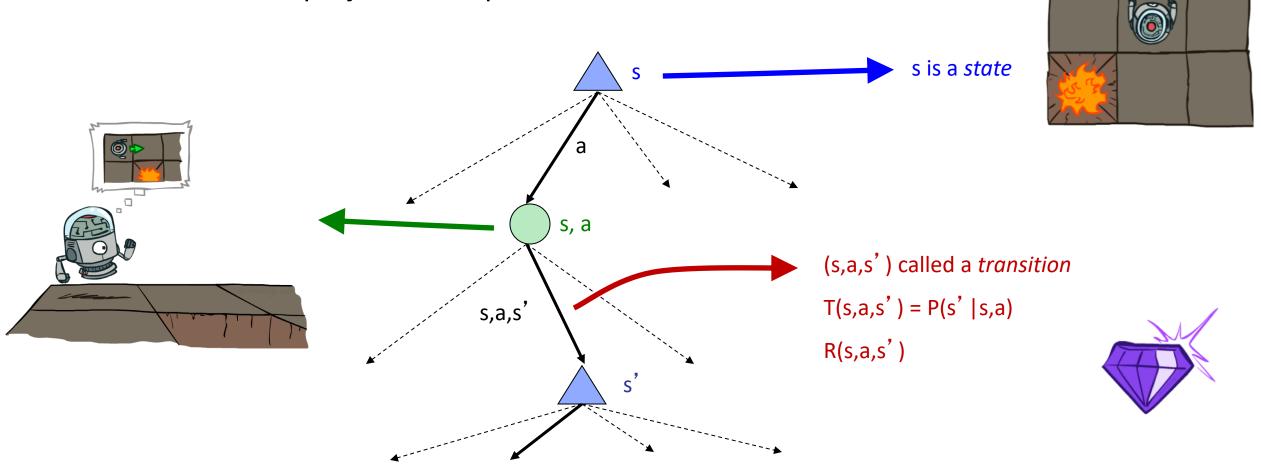

$$1\gamma = 10 \gamma^3$$

Infinite Utilities?!

- Problem: What if the game lasts forever? Do we get infinite rewards?
- Solutions:
 - Finite horizon: (similar to depth-limited search)
 - Terminate episodes after a fixed T steps (e.g. life)
 - Gives nonstationary policies (π depends on time left)
 - Discounting: use $0 < \gamma < 1$ $U([r_0, \dots r_\infty]) = \sum_{t=0}^{\infty} \gamma^t r_t \le R_{\text{max}}/(1 \gamma)$
 - Smaller γ means smaller "horizon" shorter term focus
 - Absorbing state: guarantee that for every policy, a terminal state will eventually be reached (like "overheated" for racing)

MDP Search Trees

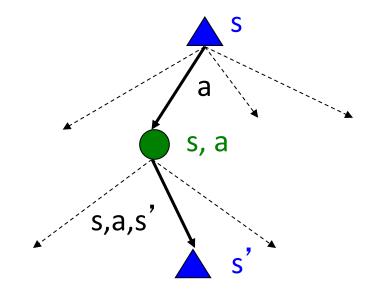

Each MDP state projects an expectimax-like search tree

Recap: Defining MDPs

Markov decision processes:

- o Set of states S
- o Start state s₀
- o Set of actions A
- o Transitions P(s' | s,a) (or T(s,a,s'))
- o Rewards R(s,a,s') (and discount γ)

MDP quantities so far:

- Policy = Choice of action for each state
- o Utility = sum of (discounted) rewards

Next Time: Solving MDPs
