#### **Uncertain Outcomes**

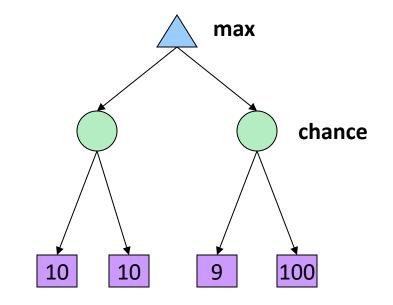

#### Worst-Case vs. Average Case

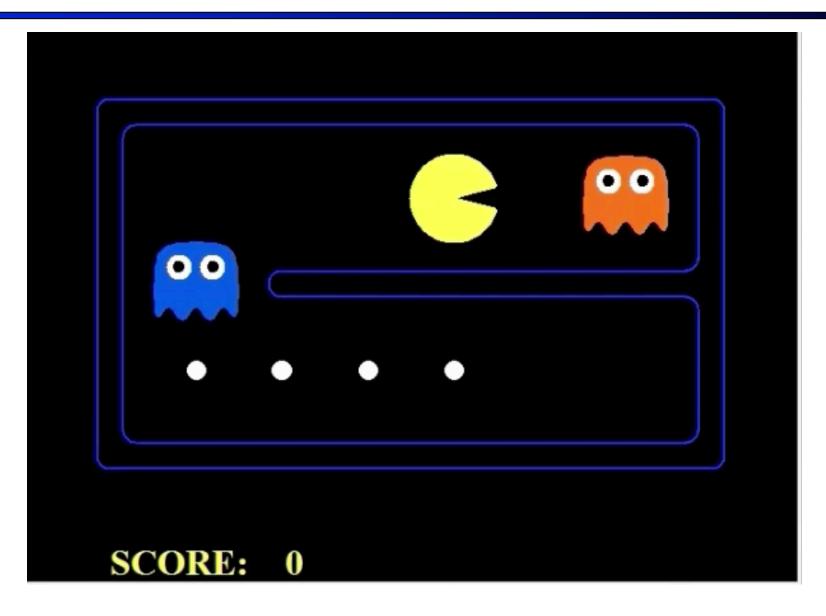

#### Idea: Uncertain outcomes controlled by chance, not an adversary!

## **Expectimax Search**

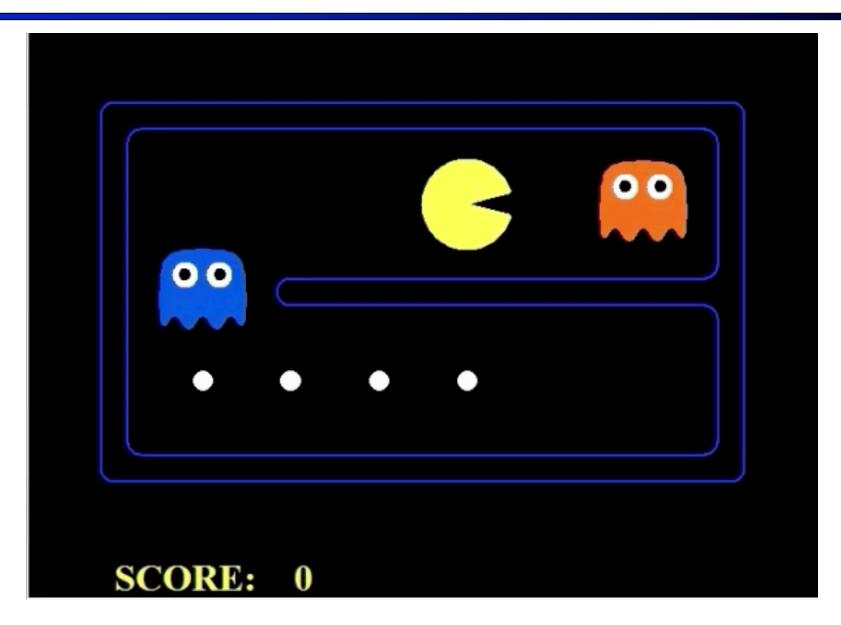

- Why wouldn't we know what the result of an action will be?
  - Explicit randomness: rolling dice
  - Unpredictable opponents: the ghosts respond randomly
  - Actions can fail: when moving a robot, wheels might slip
- Values should now reflect average-case (expectimax) outcomes, not worst-case (minimax) outcomes
- Expectimax search: compute the average score under optimal play
  - Max nodes as in minimax search
  - Chance nodes are like min nodes but the outcome is uncertain
  - Calculate their expected utilities
  - I.e. take weighted average (expectation) of children
- Later, we'll learn how to formalize the underlying uncertainresult problems as Markov Decision Processes

## Video of Demo Min vs. Exp (Min)

## Video of Demo Min vs. Exp (Exp)

## Expectimax Pseudocode

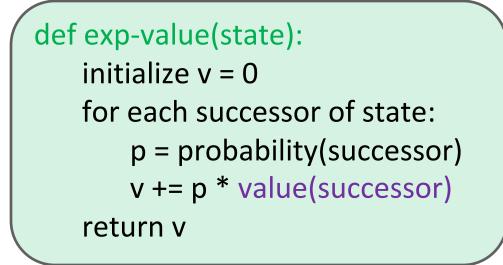

#### def value(state):

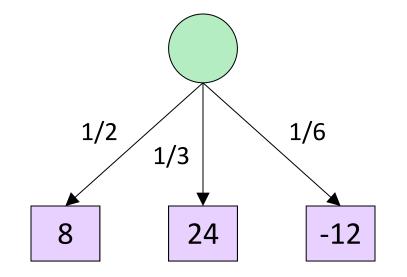

if the state is a terminal state: return the state's utility if the next agent is MAX: return max-value(state) if the next agent is EXP: return exp-value(state)

```
def max-value(state):
initialize v = -∞
for each successor of state:
    v = max(v, value(successor))
return v
```

def exp-value(state):
initialize v = 0
for each successor of state:
 p = probability(successor)
 v += p \* value(successor)
return v

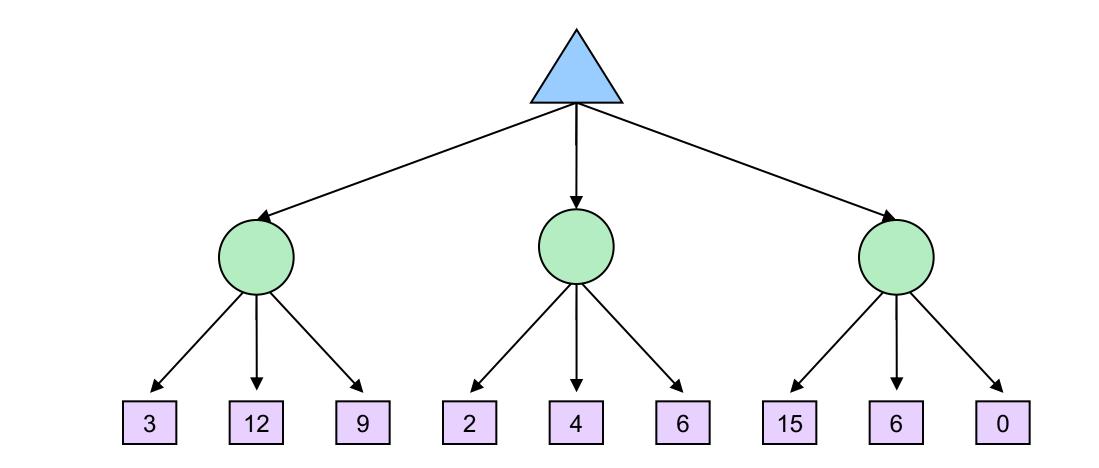

#### **Expectimax Pseudocode**

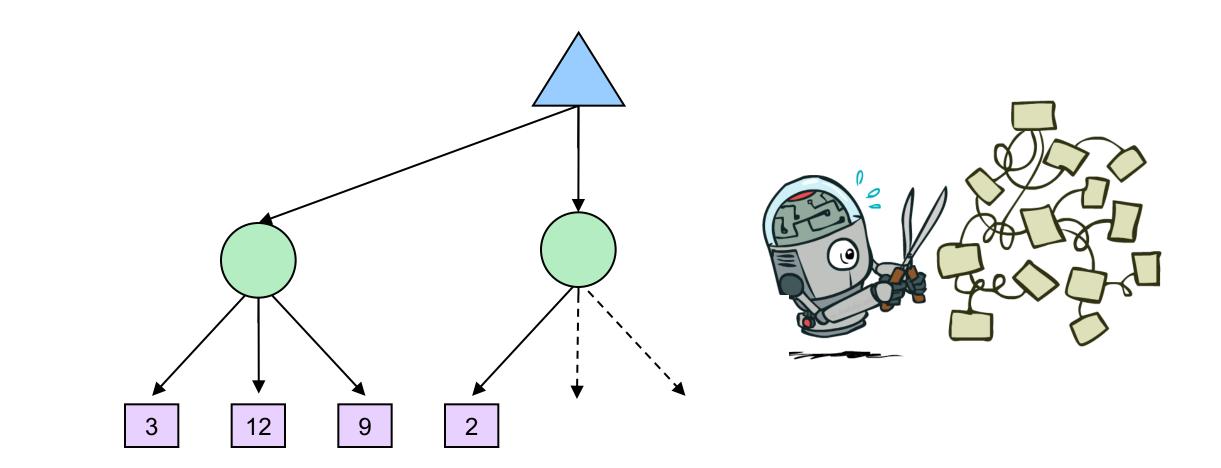

v = (1/2) (8) + (1/3) (24) + (1/6) (-12) = 10

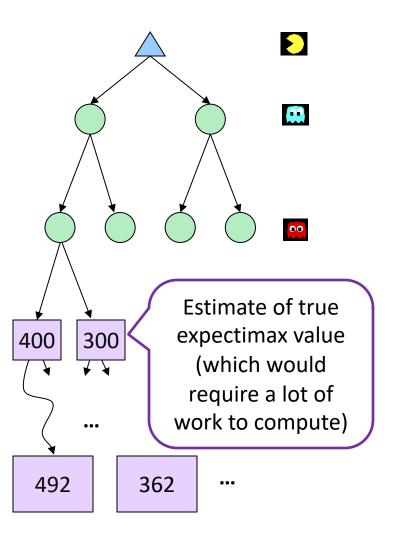

#### Expectimax Example

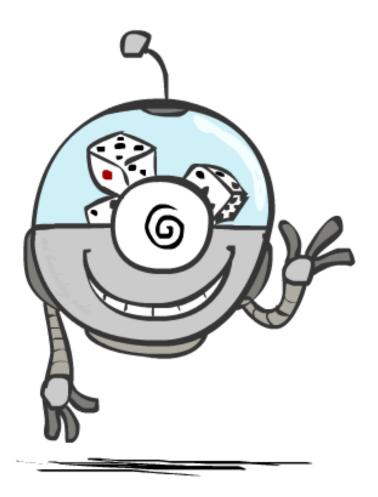

## Expectimax Pruning?

#### **Depth-Limited Expectimax**

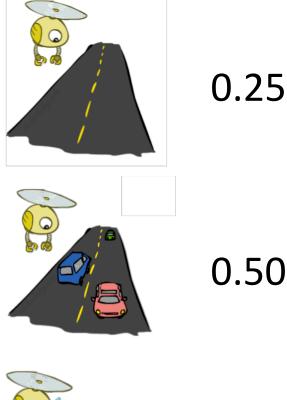

## Probabilities

# **Reminder:** Probabilities

- A random variable represents an event whose outcome is unknown
- A probability distribution is an assignment of weights to outcomes
- Example: Traffic on freeway
  - Random variable: T = whether there's traffic
  - Outcomes: T in {none, light, heavy}
  - Distribution: P(T=none) = 0.25, P(T=light) = 0.50, P(T=heavy) = 0.25
- Some laws of probability (more later):
  - Probabilities are always non-negative
  - Probabilities over all possible outcomes sum to one
- As we get more evidence, probabilities may change:
  - P(T=heavy) = 0.25, P(T=heavy | Hour=8am) = 0.60
  - We'll talk about methods for reasoning and updating probabilities later

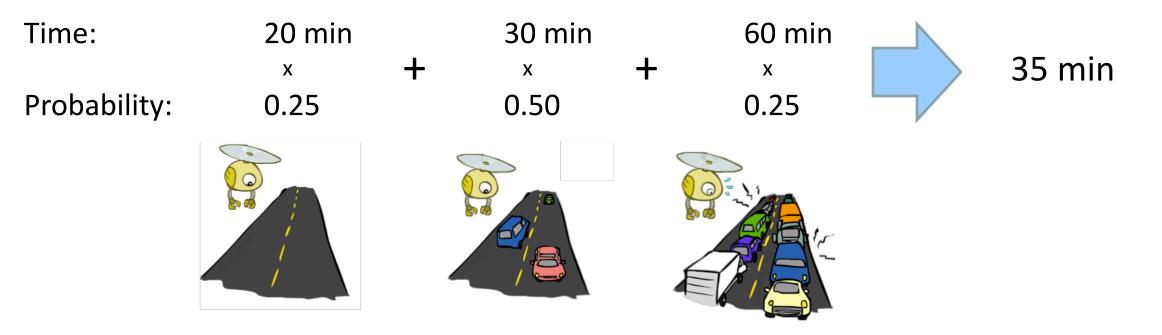

# **Reminder: Expectations**

Ч С

- The expected value of a function of a random variable is the average, weighted by the probability distribution over outcomes
- Example: How long to get to the airport?

## What Probabilities to Use?

- In expectimax search, we have a probabilistic note of how the opponent (or environment) will behany state
  - Model could be a simple uniform distribution (roll a diff)
  - Model could be sophisticated and require a great deal of computation
  - We have a chance node for any outcome out of our contor opponent or environment
  - The model might say that adversarial actions are likely!
- For now, assume each chance node magically comes along with probabilities that specify the distribution over its outcomes

Having a probabilistic belief about another agent's action does not mean that the agent is flipping any coins!

# **Quiz: Informed Probabilities**

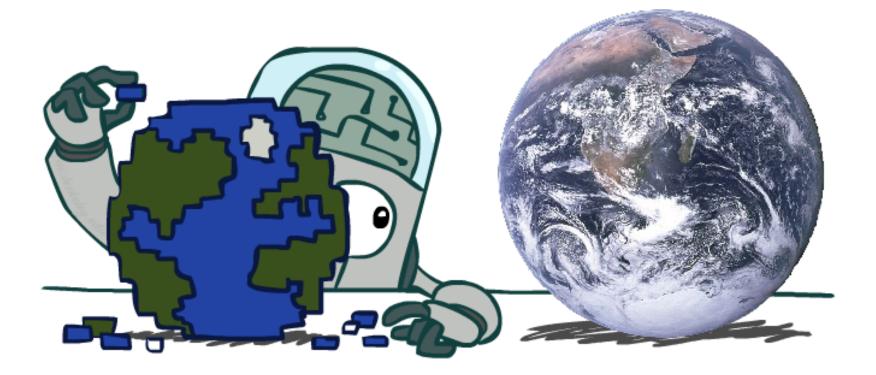

- Let's say you know that your opponent is actually running a depth 2 minimax, using the result 80% of the time, and moving randomly otherwise
- Question: What tree search should you use?

Answer: Expectimax!

- To figure out EACH chance node's probabilities, you have to run a simulation of your opponent
- This kind of thing gets very slow very quickly
- Even worse if you have to simulate your opponent simulating you...
- ... except for minimax, which has the nice property that it all collapses into one game tree

## **Modeling Assumptions**

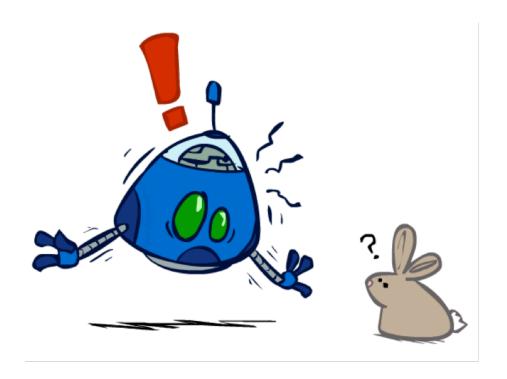

# The Dangers of Optimism and Pessimism

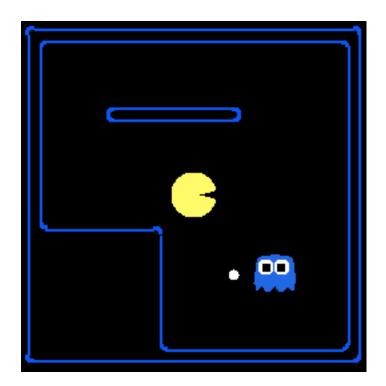

Dangerous Optimism Assuming chance when the world is adversarial

Dangerous Pessimism Assuming the worst case when it's not likely

### Assumptions vs. Reality

	Adversarial Ghost	Random Ghost
Minimax	Won 5/5	Won 5/5
Pacman	Avg. Score: 483	Avg. Score: 493
Expectimax	Won 1/5	Won 5/5
Pacman	Avg. Score: -303	Avg. Score: 503

Results from playing 5 games

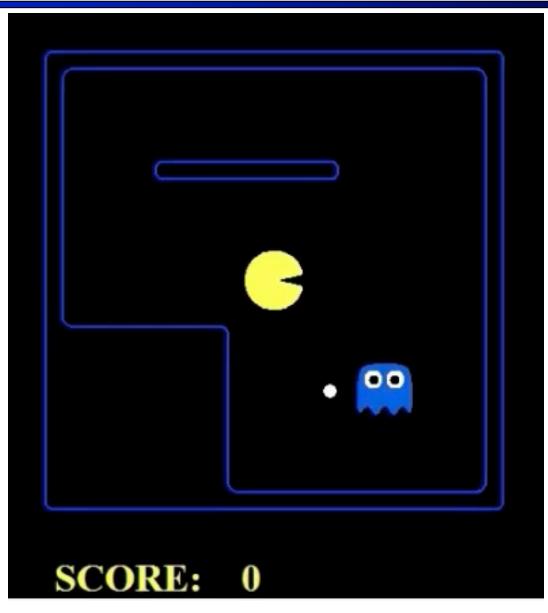

Pacman used depth 4 search with an eval function that avoids trouble Ghost used depth 2 search with an eval function that seeks Pacman

# Other Game Types

# Mixed Layer Types

- E.g. Backgammon
- Expectiminimax
  - Environment is an extra "random agent" player that moves after each min/max agent
  - Each node computes the appropriate combination of its children

# Example: Backgammon

- Dice rolls increase b: 21 possible rolls with 2 dice
  - Backgammon ≈ 20 legal moves
  - Depth 2 = 20 x (21 x 20)<sup>3</sup> = 1.2 x 10<sup>9</sup>
- As depth increases, probability of reaching a given search node shrinks
  - So usefulness of search is diminished
  - So limiting depth is less damaging
  - But pruning is trickier...
- Historic AI: TDGammon uses depth-2 search + very good evaluation function + reinforcement learning: world-champion level play
- 1<sup>st</sup> AI world champion in any game!

# **Multi-Agent Utilities**

- What if the game is not zero-sum, or has multiple players?
- Generalization of minimax:
  - Terminals have utility tuples
  - Node values are also utility tuples
  - Each player maximizes its own component
  - Can give rise to cooperation and competition dynamically...
