HW 1: Warmup Missionaries and Cannibals

- Solve the Missionary-Cannibal Problem (with 3 missionaries and 3 cannibals) with a RECURSIVE DEPTH-FIRST SEARCH as follows:
 - You MUST use a recursive depth first search
 - No ancestor repeated states in a path
 - Keep counts of illegal states (cannibals eat missionaries), repeated states, total states searched
 - Use Python
 - Comment on each method and important code sections
 - Print all paths from start to goal
 - Print the final 3 counts.
- Due Jan 16 11:59pm. Late date Jan 18 11:59pm
- Your work must be YOUR OWN.

Informed (Heuristic) Search

Idea: be **smart** about what paths to try.

Blind Search vs. Informed Search

• What's the difference?

 How do we formally specify this?
 A node is selected for expansion based on an evaluation function that estimates cost to goal.

General Tree Search Paradigm

function tree-search(root-node)
fringe ← successors(root-node)
while (notempty(fringe))
 {node ← remove-first(fringe)
 state ← state(node)
 if goal-test(state) return solution(node)
 fringe ← insert-all(successors(node),fringe) }
return failure
end tree-search

How do we order the successor list?

Best-First Search

- Use an evaluation function f(n) for node n.
- Always choose the node from fringe that has the lowest f value.

Heuristics

- What is a heuristic?
- What are some examples of heuristics we use?

We'll call the heuristic function h(n).

Greedy Best-First Search

- f(n) = h(n)
- What does that mean?

• What is it ignoring?

Romanian Route Finding

Problem

- Initial State: Arad
- Goal State: Bucharest
- -c(s,a,s') is the length of the road from s to s'
- Heuristic function: h(s) = the straight line distance from s to Bucharest

Original Road Map of Romania

What's the real shortest path from Arad to Bucharest?₉ What's the distance on that path?

Greedy Search in Romania

10

Greedy Best-First Search

Is greedy search optimal?

• Is it complete?

No, can get into infinite loops in tree search. Graph search is complete for finite spaces.

- What is its worst-case complexity for a tree search with branching factor b and maximum depth m?
 - time O(b^m)

- space O(b^m)

Greedy Best-First Search

• When would we use greedy best-first search or greedy approaches in general?

A* Search

- Hart, Nilsson & Rafael 1968
 - Best-first search with f(n) = g(n) + h(n)
 where g(n) = sum of edge costs from start to n
 and h(n) = estimate of lowest cost path n-->goal
 - If h(n) is admissible then search will find optimal solution.

Never overestimates the true cost of any solution which can be reached from a node.

Space bound since the queue must be maintained.

Back to Romania

A* for Romanian Shortest Path

8 Puzzle Example

- f(n) = g(n) + h(n)
- What is the usual g(n)?
- two well-known h(n)'s
 - -h1 = the number of misplaced tiles
 - h2 = the sum of the distances of the tiles from their goal positions, using city block distance, which is the sum of the horizontal and vertical distances (Manhattan Distance)

8 Puzzle Using Number of Misplaced Tiles

1 8 7	2 6	3 4 5	283 14 765	Exercise: What are its children and their f, g, h?
	/			

Optimality of A* with Admissibility (h never overestimates the cost to the goal)

Suppose a suboptimal goal G2 has been generated and is in the queue. Let n be an unexpanded node on the shortest path to an optimal goal G1.

f(n) = g(n) + h(n)	
≤ g(G1)	Why?
< g(G2)	G2 is suboptimal
= f(G2)	f(G2) = g(G2)
So $f(n) < f(G2)$ and	A* will never select

G2 for expansion.

Optimality of A* with Consistency (stronger condition)

- h(n) is consistent if
 - for every node n
 - for every successor n' due to legal action a
 - $-h(n) \le c(n,a,n') + h(n')$

• Every consistent heuristic is also admissible.

Algorithms for A*

- Since Nillsson defined A* search, many different authors have suggested algorithms.
- Using Tree-Search, the optimality argument holds, but you search too many states.
- Using Graph-Search, it can break down, because an optimal path to a repeated state can be discarded if it is not the first one found.
- One way to solve the problem is that whenever you come to a repeated node, discard the longer path to it.

The Rich/Knight Implementation

- a node consists of
 - state
 - g, h, f values
 - list of successors
 - pointer to parent
- OPEN is the list of nodes that have been generated and had h applied, but not expanded and can be implemented as a priority queue.
- CLOSED is the list of nodes that have already been expanded.

2) repeat until goal (or time limit or space limit)

- if OPEN is empty, fail
- BESTNODE <- node on OPEN with lowest f
- if BESTNODE is a goal, exit and succeed
- remove BESTNODE from OPEN and add it to CLOSED
- generate successors of BESTNODE

for each successor s do

- 1. set its parent field
- 2. compute g(s)
- 3. if there is a node OLD on OPEN with the same state info as s

{ add OLD to successors(BESTNODE)
 if g(s) < g(OLD), update OLD and
 throw out s }</pre>

Rich/Knight/Tanimoto

- 4. if (s is not on OPEN and there is a node OLD on CLOSED with the same state info as s
 - { add OLD to successors(BESTNODE)

if g(s) < g(OLD), update OLD,
 remove it from CLOSED
 and put it on OPEN, throw out s</pre>

5. If s was not on OPEN or CLOSED { add s to OPEN add s to successors(BESTNODE) calculate g(s), h(s), f(s) }

end of repeat loop
