

# SLAM: Simultaneous Localization and Mapping

Instructor: Chris Mavrogiannis

TAs: Kay Ke, Gilwoo Lee, Matt Schmittle

\*Slides based on or adapted from Sanjiban Choudhury, Dieter Fox, Michael Kaess

# The SLAM problem

Robot is moving through a static unknown environment

Given a series of **controls** and **measurements**,  
estimate **state** and **map**

# What if I just integrate controls?

# Spilling the beans on SLAM

Let's assume this was the ground truth....

→ Ground truth

# Spilling the beans on SLAM

Odometry is really really noisy!

→ Ground truth

→ Odometry

# Spilling the beans on SLAM

Measurements can help correct this somewhat

Ground truth

Odometry

Measurement  
correction <sub>7</sub>

# Spilling the beans on SLAM

Relative error accumulates ...

Ground truth

Odometry

Measurement  
correction <sub>g</sub>

# Spilling the beans on SLAM

Eventually robot comes back to a familiar place .... loop closure!

Ground truth

Odometry

Measurement  
correction<sub>g</sub>

# Spilling the beans on SLAM

If we are filtering, we can only fix the last pose estimate

Ground truth

Odometry

Measurement  
correction<sub>10</sub>

# Spilling the beans on SLAM

If we are **optimizing**, we can backprop errors in time!

Ground truth

Odometry

Measurement

# Today's objective

1. How do we solve the chicken-or-egg problem in SLAM?
2. SLAM as an optimization instead of filtering

# Bayes filter is a powerful tool

Localization

Mapping

SLAM

POMDP

# Assembling Bayes filter

# Tasks that we will cover

---

## Tasks

## Belief Representation

## Probabilistic Models

---

### Localization

$P(\text{pose} \mid \text{data})$

(Week 3)

Gaussian / Particles

Motion model  
Measurement model

### Mapping

$P(\text{map} \mid \text{data})$

(Week 4)

Discrete (binary)

Inverse measurement model

### SLAM

$P(\text{pose, map} \mid \text{data})$

(Week 4)

Particles+GridMap  
(pose, map)

Motion model,  
measurement model,  
*correspondence model*

# SLAM as just another Bayes filtering problem

Task: SLAM  
 $P(\text{map}, \text{pose} \mid \text{data})$

What is the data?

$u_{1:t}, z_{1:t}$

What is the belief representation?

$$P(x_t, m \mid u_{1:t}, z_{1:t})$$

# Different map representations

We are free to use any of the map representations we discussed

Feature maps

Grid maps

Surface maps

# Why is SLAM hard?

Chicken-or-egg problem:

Given a map, we can localize

Given the pose, we can build map

# Graphical model of SLAM

If SLAM can be expressed as a  
Bayes filtering problem,  
let's use our favorite Bayes filter...

Particle Filter!

# Generalized particle filters

**Step 0:** Start with a set of particles

$$bel(x_{t-1}) = \{x_{t-1}^1, x_{t-1}^2, \dots, x_{t-1}^M\}$$

**Step 1:** Sample particles from proposal distribution

$$\overline{bel}(x_t) = \{\bar{x}_t^1, \dots, \bar{x}_t^M\}$$

**Step 2:** Compute importance weights

$$w_t^k = \frac{bel(x_t)}{\overline{bel}(x_t)} \left( = \eta P(z_t | x_t) \right)$$

**Step 3:** Resampling

Draw M samples from weighted distribution

# Problem: Space of maps too large!!

$$P(x_t, m | u_{1:t}, z_{1:t})$$

How big is this  
space?

$$\left( 2^M \right)$$

If we were to sample particles, what is the likelihood that they would explain the measurements??

$$P(z_t | m, x_t)$$

# Key idea: Exploit dependencies

Even if a space is absurdly large, dependencies within the space can significantly shrink the space of possibilities we should consider.

# Key idea: Exploit dependencies

Is there a dependency in this gigantic combined state space?

Yes!

The map depends on the history of poses of the robot

# Rao-Blackwellization

Factorization to exploit dependencies between variables

$$P(a, b) = P(b|a)P(a)$$

If  $P(b|a)$  can be computed efficiently

Represent

$$P(a)$$

with samples

Compute

$$P(b|a)$$

for every sample

# Applying the factorization trick

$$P(x_{1:t}, m | z_{1:t}, u_{1:t})$$

state  
history          map          data

$$= P(x_{1:t} | z_{1:t}, u_{1:t}) P(m | x_{1:t}, z_{1:t}, u_{1:t})$$

state                          data                          state                          data  
history                          map                          history

$$= P(x_{1:t} | z_{1:t}, u_{1:t}) \prod_{i=1}^N P(m_i | x_{1:t}, z_{1:t})$$

state                          data  
history

(Particle filter to estimate this)

(Occupancy map)

# How do we compute a PF over **state history**?

For simplicity, each particle only stores the current state at timestep  $t$   
(just like you did in your assignment)

However the weights of the particle are computed based on  
**its path through time.**

# How do we compute a PF over **state history**?

Let's jump straight to the importance sampling step

$$\begin{aligned}w_t &= \frac{bel(x_{1:t})}{\overline{bel}(x_{1:t})} = \frac{P(x_{1:t} | z_t, z_{1:t-1}, u_{1:t})}{P(x_{1:t} | z_{1:t-1}, u_{1:t})} \\&\propto \frac{P(z_t | x_{1:t}, z_{1:t-1}, u_{1:t}) P(x_{1:t} | z_{1:t-1}, u_{1:t})}{P(x_{1:t} | z_{1:t-1}, u_{1:t})} \\&\propto P(z_t | x_t, x_{1:t-1}, z_{1:t-1}, u_{1:t}) \\&\propto \sum_m P(z_t | x_t, m) P(m | x_{1:t-1}, z_{1:t-1}, u_{1:t}) \\&\approx P(z_t | x_t, \hat{m}) \\&\quad \text{(meas)} \quad \text{(most likely map from prev timestep)}\end{aligned}$$

where  $\hat{m} = \arg \max_m P(m | x_{1:t-1}, z_{1:t-1}, u_{1:t-1})$

# FastSLAM

***OpenSLAM***  
*Give your algorithm to the community*

<https://openslam-org.github.io/>

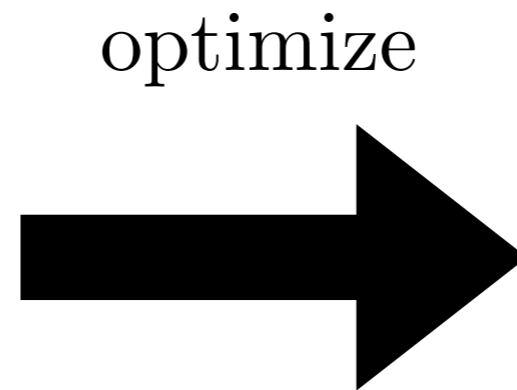

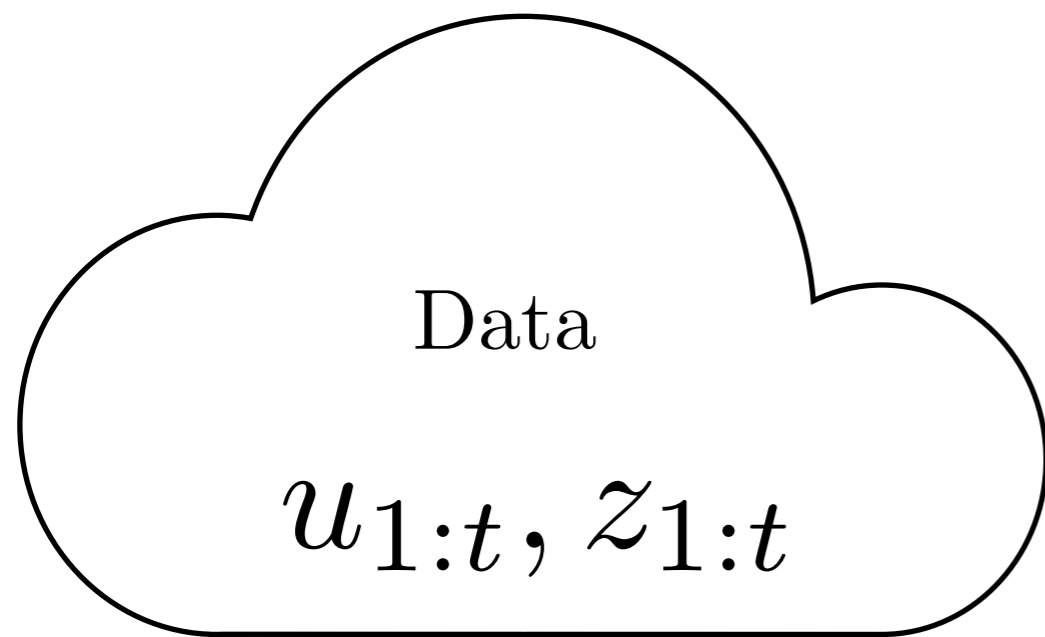

Do we really need a probability distribution?

$$P(x_{1:t}, m)$$

Or are does a maximum a posteriori estimate suffice?

$$\hat{x}_{1:t}, \hat{m} = \arg \max_{x_{1:t}, m} P(x_{1:t}, m)$$
