

CSE 484 (Winter 2011)

# Introduction to Cryptography (Continued)

---

Tadayoshi Kohno

Thanks to Dan Boneh, Dieter Gollmann, John Manferdelli, John Mitchell, Vitaly Shmatikov, Bennet Yee, and many others for sample slides and materials ...

# Goals for Today

---

- ◆ Under the hood: Symmetric cryptography  
(Continued)

# Announcements / Reminders

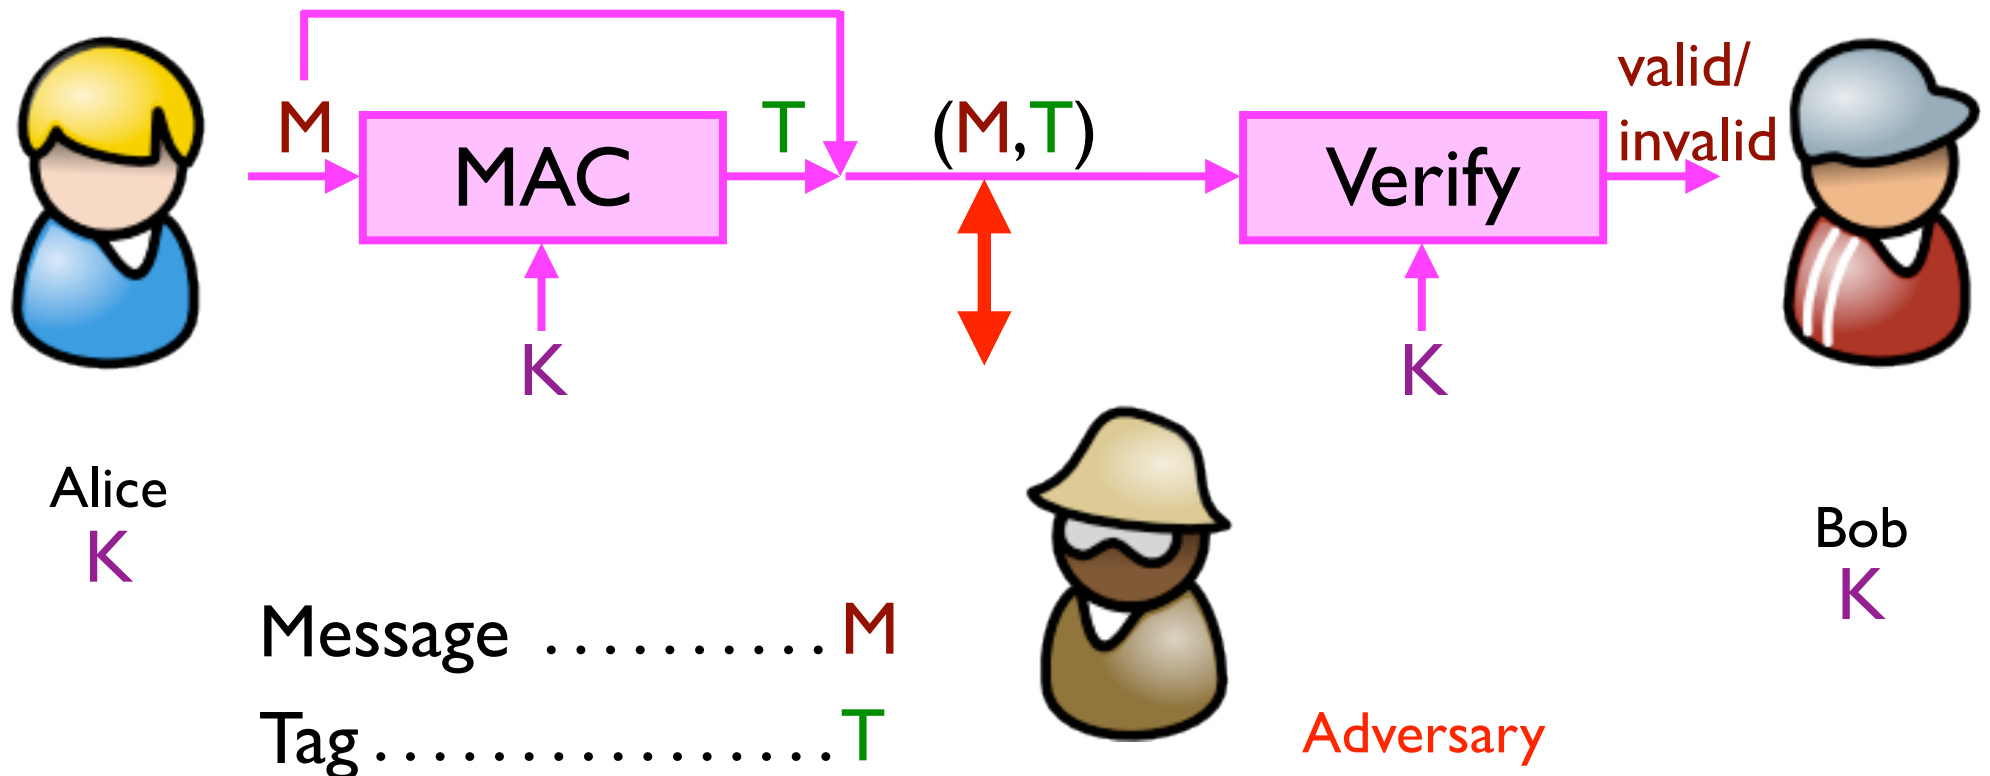

---

- ◆ Lab 1 due on Wednesday (5pm)
  - Extra TA office hours tomorrow
- ◆ HW 2 now online (Due Feb 11)
  - Forgot to add extra credit (2DES problems) -- will add ASAP
- ◆ Lab 2 to be announced on Wednesday (discussed in quiz section on Thursday)

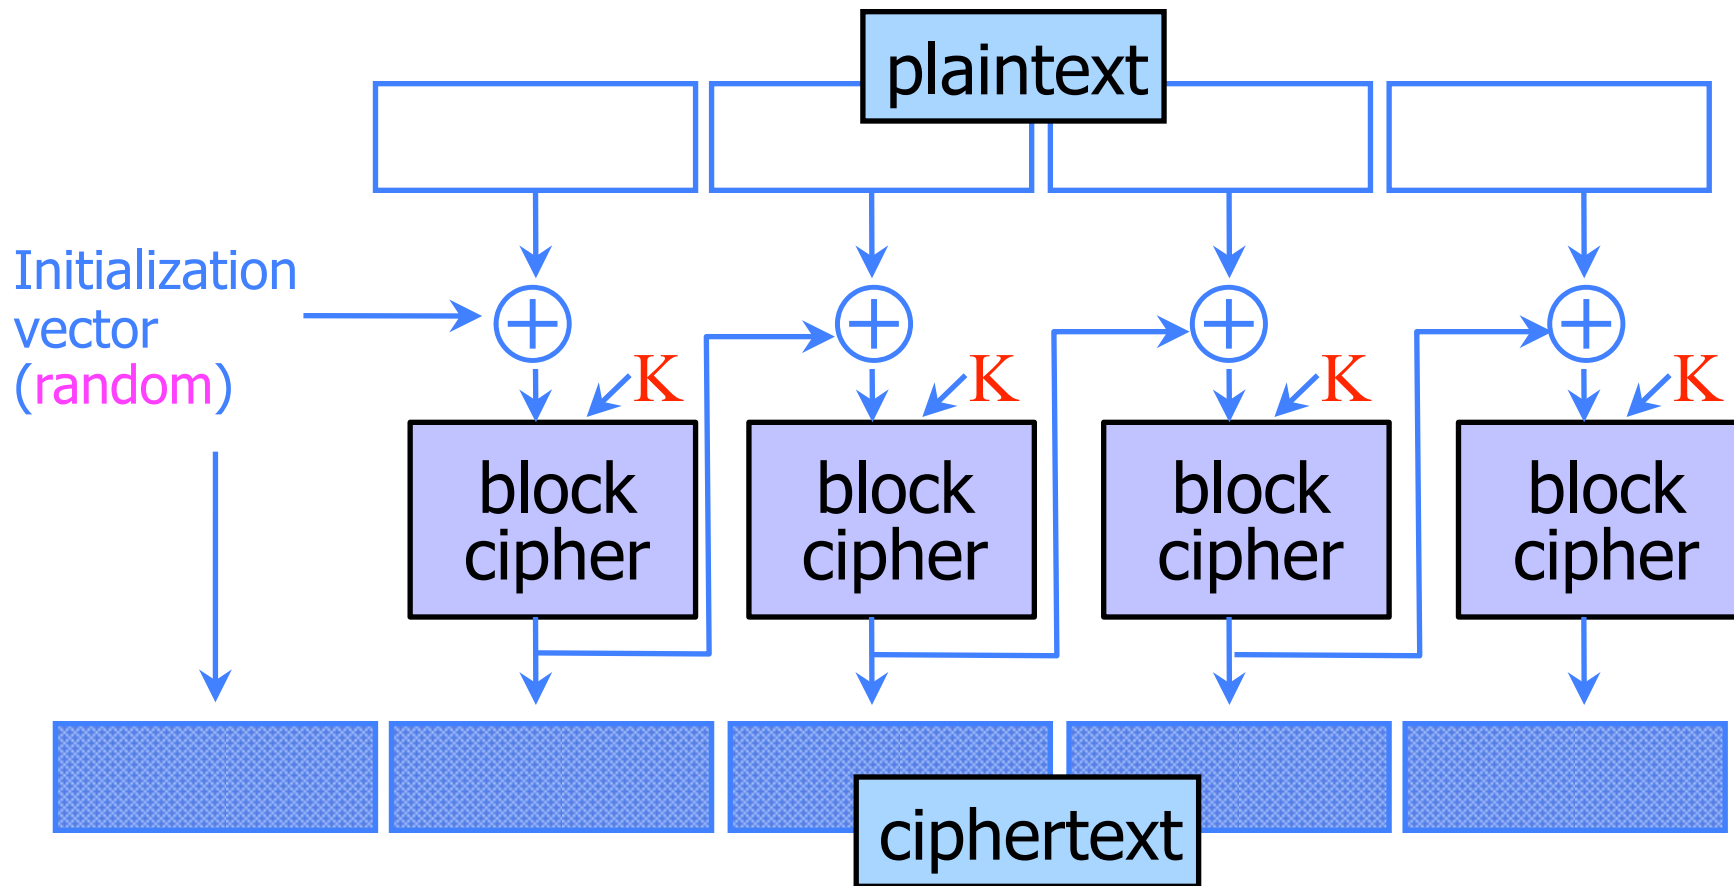

# Achieving Integrity (Symmetric)

Message authentication schemes: A tool for protecting integrity.

(Also called message authentication codes or MACs.)

# CBC Mode: Encryption

- ◆ Identical blocks of plaintext encrypted differently
- ◆ Last cipherblock depends on entire plaintext
  - Still does not guarantee integrity

# CBC-MAC

- ◆ Not secure when system may MAC messages of different lengths.
  - Encode length at beginning: Whiteboard example
  - Use a derivative called CMAC
- ◆ Internal collisions and birthday attacks: Whiteboard example

# Hash Functions: Main Idea

---

## ◆ H is a lossy compression function

- **Collisions:**  $h(x)=h(x')$  for distinct inputs  $x, x'$
- Result of hashing should "look random" (make this precise later)
  - Intuition: half of digest bits are "1"; any bit in digest is "1" half the time

## ◆ **Cryptographic hash function** needs a few properties...

# One-Way

---

- ◆ Intuition: hash should be hard to invert
  - “Preimage resistance”
  - Let  $h(x')=y \in \{0,1\}^n$  for a random  $x'$
  - Given  $y$ , it should be hard to find any  $x$  such that  $h(x)=y$
- ◆ How hard?
  - Brute-force: try every possible  $x$ , see if  $h(x)=y$
  - SHA-1 (common hash function) has 160-bit output
    - Expect to try  $2^{159}$  inputs before finding one that hashes to  $y$ .

# Collision Resistance

---

- ◆ Should be hard to find distinct  $x, x'$  such that  $h(x)=h(x')$ 
  - Brute-force collision search is only  $O(2^{n/2})$ , not  $O(2^n)$
  - For SHA-1, this means  $O(2^{80})$  vs.  $O(2^{160})$
- ◆ Birthday paradox (informal)
  - Let  $t$  be the number of values  $x, x', x'' \dots$  we need to look at before finding the first pair  $x, x'$  s.t.  $h(x)=h(x')$
  - What is probability of collision for each pair  $x, x'$ ?  $1/2^n$
  - How many pairs would we need to look at before finding the first collision?  $O(2^n)$
  - How many pairs  $x, x'$  total?  $\text{Choose}(t, 2) = t(t-1)/2 \sim O(t^2)$
  - What is  $t$ ?  $2^{n/2}$

# One-Way vs. Collision Resistance

---

## ◆ One-wayness does not imply collision resistance

- Suppose  $g$  is one-way
- Define  $h(x)$  as  $g(x')$  where  $x'$  is  $x$  except the last bit
  - $h$  is one-way (to invert  $h$ , must invert  $g$ )
  - Collisions for  $h$  are easy to find: for any  $x$ ,  $h(x0)=h(x1)$

## ◆ Collision resistance does not imply one-wayness

- Suppose  $g$  is collision-resistant
- Define  $h(x)$  to be  $0x$  if  $x$  is  $n$ -bit long,  $1g(x)$  otherwise
  - Collisions for  $h$  are hard to find: if  $y$  starts with  $0$ , then there are no collisions, if  $y$  starts with  $1$ , then must find collisions in  $g$
  - $h$  is not one way: half of all  $y$ 's (those whose first bit is  $0$ ) are easy to invert (how?); random  $y$  is invertible with probab.  $1/2$

# Weak Collision Resistance

---

- ◆ Given randomly chosen  $x$ , hard to find  $x'$  such that  $h(x)=h(x')$ 
  - Attacker must find collision for a specific  $x$ . By contrast, to break collision resistance it is enough to find any collision.
  - Brute-force attack requires  $O(2^n)$  time
  - AKA **second-preimage collision** resistance
- ◆ Weak collision resistance does not imply collision resistance

# Which Property Do We Need?

---

- ◆ UNIX passwords stored as  $\text{hash}(\text{password})$ 
  - One-wayness: hard to recover the/a valid password
- ◆ Integrity of software distribution
  - Weak collision resistance (second-preimage resistance)
  - But software images are not really random...
- ◆ Auction bidding
  - Alice wants to bid  $B$ , sends  $H(B)$ , later reveals  $B$
  - One-wayness: rival bidders should not recover  $B$  (this may mean that she needs to hash some randomness with  $B$  too)
  - Collision resistance: Alice should not be able to change her mind to bid  $B'$  such that  $H(B)=H(B')$

# Common Hash Functions

---

## ◆ MD5

- 128-bit output
- Designed by Ron Rivest, used very widely
- Collision-resistance broken (summer of 2004)

## ◆ RIPEMD-160

- 160-bit variant of MD5

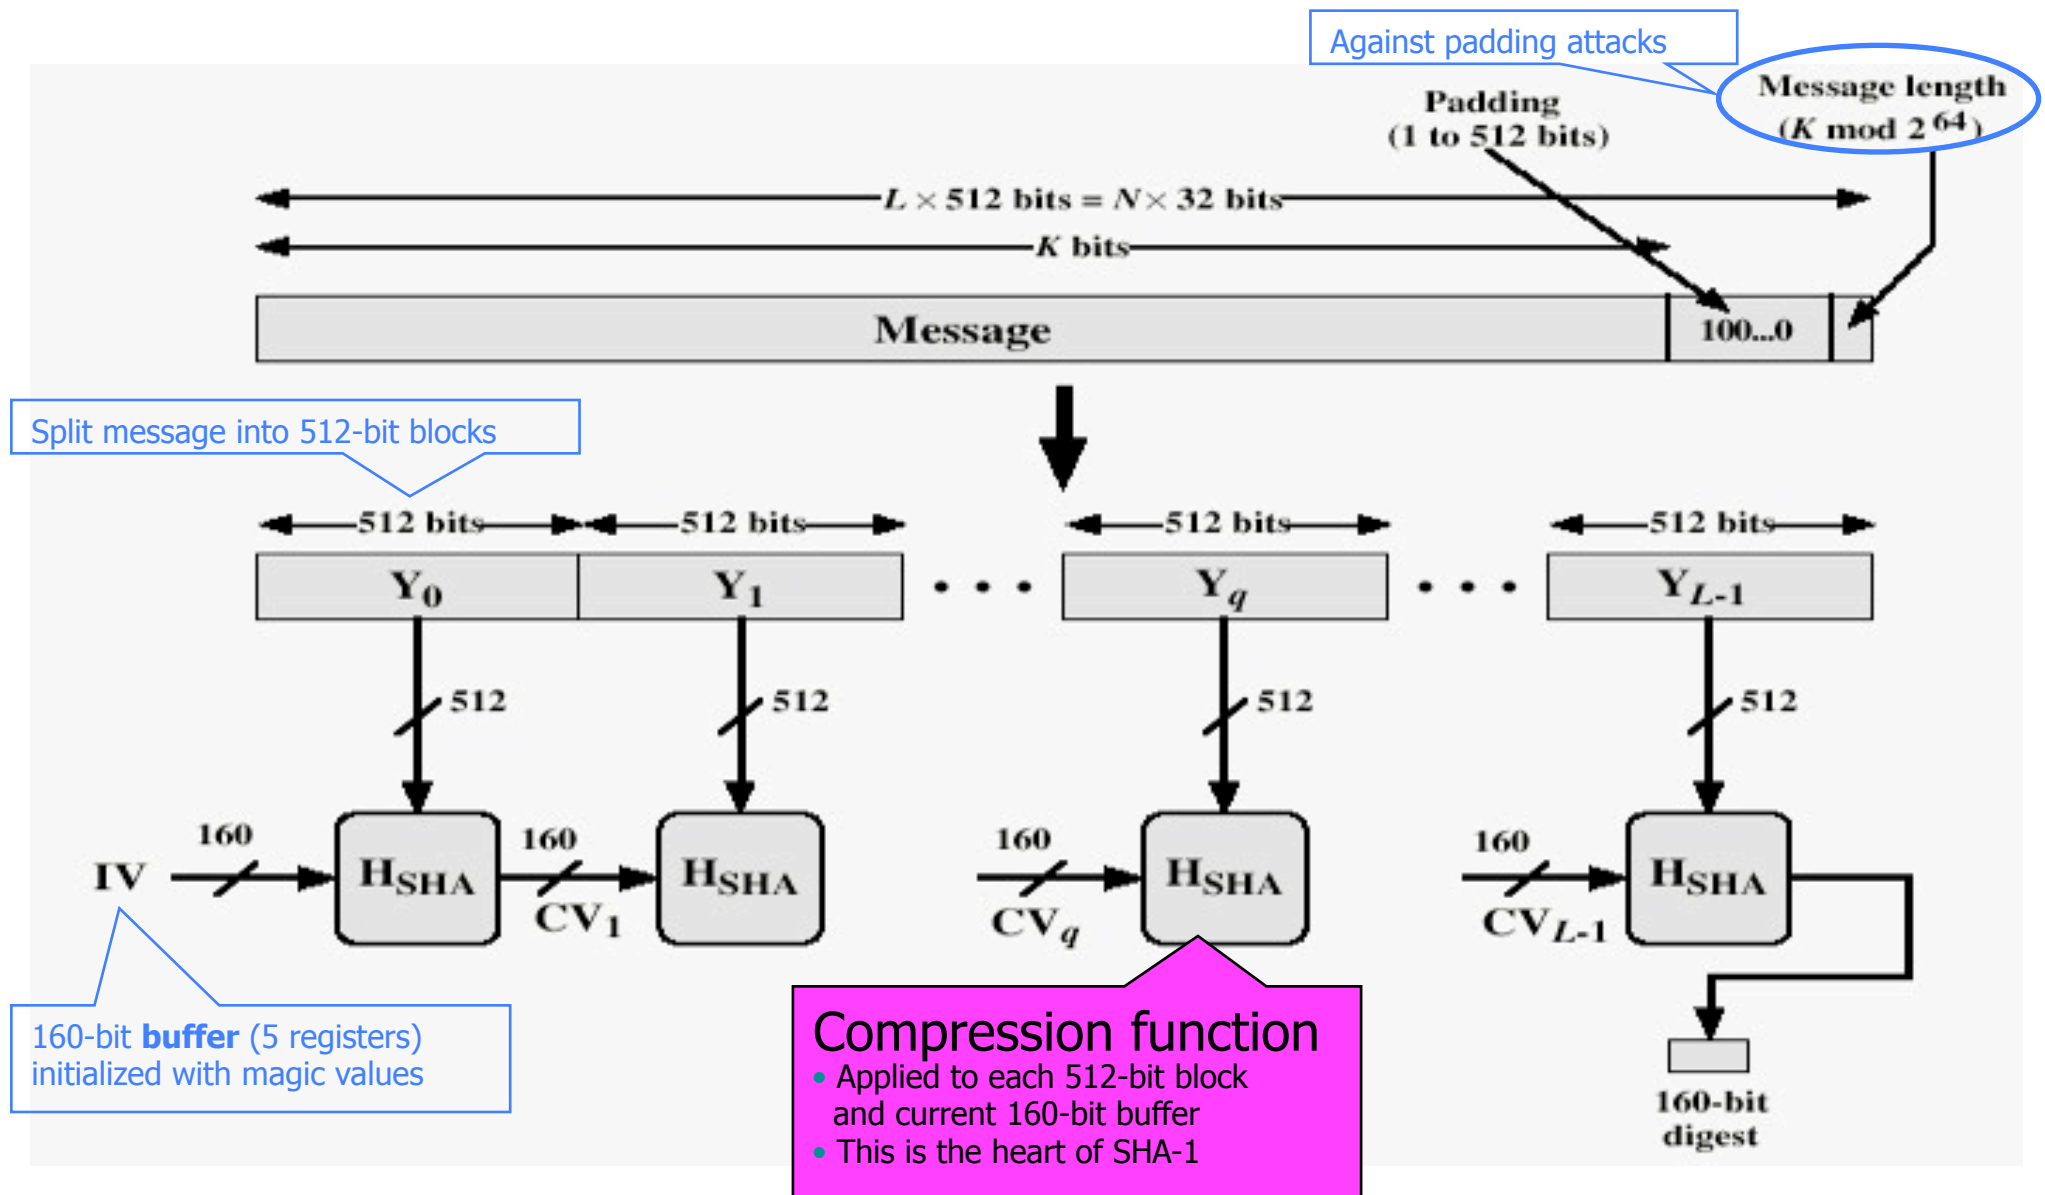

## ◆ SHA-1 (Secure Hash Algorithm)

- 160-bit output
- US government (NIST) standard as of 1993-95
- Also recently broken! (Theoretically -- not practical.)

## ◆ SHA-256, SHA-512, SHA-224, SHA-384

## ◆ SHA-3: Forthcoming.

# Basic Structure of SHA-1 (Not Required)

# How Strong Is SHA-1?

---

- ◆ Every bit of output depends on every bit of input
  - Very important property for collision-resistance
- ◆ Brute-force inversion requires  $2^{160}$  ops, birthday attack on collision resistance requires  $2^{80}$  ops
- ◆ Some recent weaknesses (2005)
  - Collisions can be found in  $2^{63}$  ops

# International Criminal Tribunal for Rwanda (Example Application)
