Side Channel Attacks

Spring 2020

Franziska (Franzi) Roesner
franzi@cs.washington.edu

Thanks to Dan Boneh, Dieter Gollmann, Dan Halperin, Yoshi Kohno, John Manferdelli, John Mitchell, Vitaly Shmatikov, Bennet Yee, and many others for sample slides and materials ...

Admin

- HW3 due today
- Project checkpoint 2 due today
- **Monday: Guest lecture** from Peter Ney (UW)
 - DNA + computer security
- **Wednesday:** Emerging tech and wrap-up
- **Friday:** No lecture, extra office hours instead

→ see also
canvas rubric
for final project

Side Channel Attacks

- Attacks based on **information that can be gleaned from the physical implementation of a system**, rather than breaking its theoretical properties
 - Initially most commonly discussed in the context of cryptosystems
 - But also prevalent in many contexts
 - E.g., we discussed the TENEX password implementation ←
 - E.g., we discussed browser fingerprinting ← *canvas*

Examples on Cryptosystems

- Timing attacks
- Power analysis
- Good overview:
http://www.nicolascourtois.com/papers/sc/side_ch_attacks.pdf

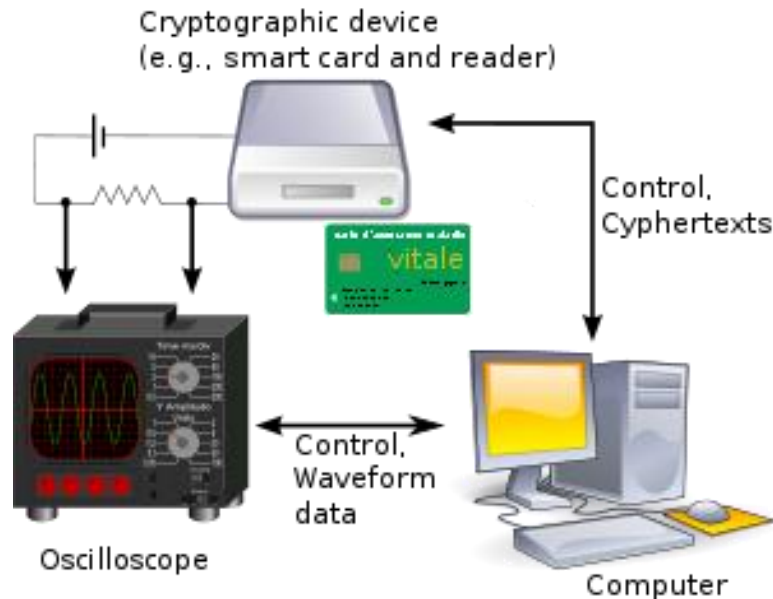

If you do something different for secret key bits 1 vs. 0, attacker can learn something...

Example Timing Attacks

- **RSA:** Leverage key-dependent timings of modular exponentiations
 - <https://www.rambus.com/timing-attacks-on-implementations-of-diffie-hellman-rsa-dss-and-other-systems/>
 - <http://crypto.stanford.edu/~dabo/papers/ssl-timing.pdf>
- **Block Ciphers:** Leverage key-dependent cache hits/misses

Power Analysis

- **Simple power analysis:** Directly read off bits from powerline traces
- **Differential power analysis:** Look for statistical differences in power traces, based on guesses of a key bit

Key Extraction via Electric Potential

Key = 1110111011...

SPECTRE

Spectre

Exploit (1) speculative execution and (2) cache timing information to **extract private information from the same process**

- Example: JavaScript running in web page
 - Until recently, iframes were in the same process as their parent pages (big effort to change this, **Site Isolation**: <https://support.google.com/chrome/answer/7623121?hl=en>)
- Note there are other variants (new ones still appearing often!)
melt down

Instruction Speculation

Many steps (cycles) to execute one instruction; time flows left to right →

Go Faster! Pipelining, branch prediction, & instruction speculation

If speculation correct: Commit architectural changes of **and** (register) & **store** (memory) -- quick!

If mis-speculate: Abort architectural changes (registers, memory); go in other branch direction

Speculation affects the cache!

Cache Timing Attacks

- **Basic idea:** Manipulate cache to a known state, wait for victim activity, then examine what has changed.
- Example: “Flush + Reload”
 1. Flush relevant addresses from cache
 2. Wait for victim (here: execute Spectre attack)
 3. Reload relevant addresses, time accesses

If timing was fast, victim accessed relevant address; if timing was slow, victim did not.

```

if (x < array1_size)
  y = array2[array1[x] * 4096];

```

- Given code above, suppose that:
 - Adversary can run code, in the same process.
 - Adversary can control the value x.
 - Adversary has access to array2.
 - Adversary cannot just read arbitrary memory in the process.
 - There is some secret value, elsewhere in the process, that the adversary would like to learn.
 - Specifically: **Attacker's goal is to read secret memory at address array1+x, for some too-large x**

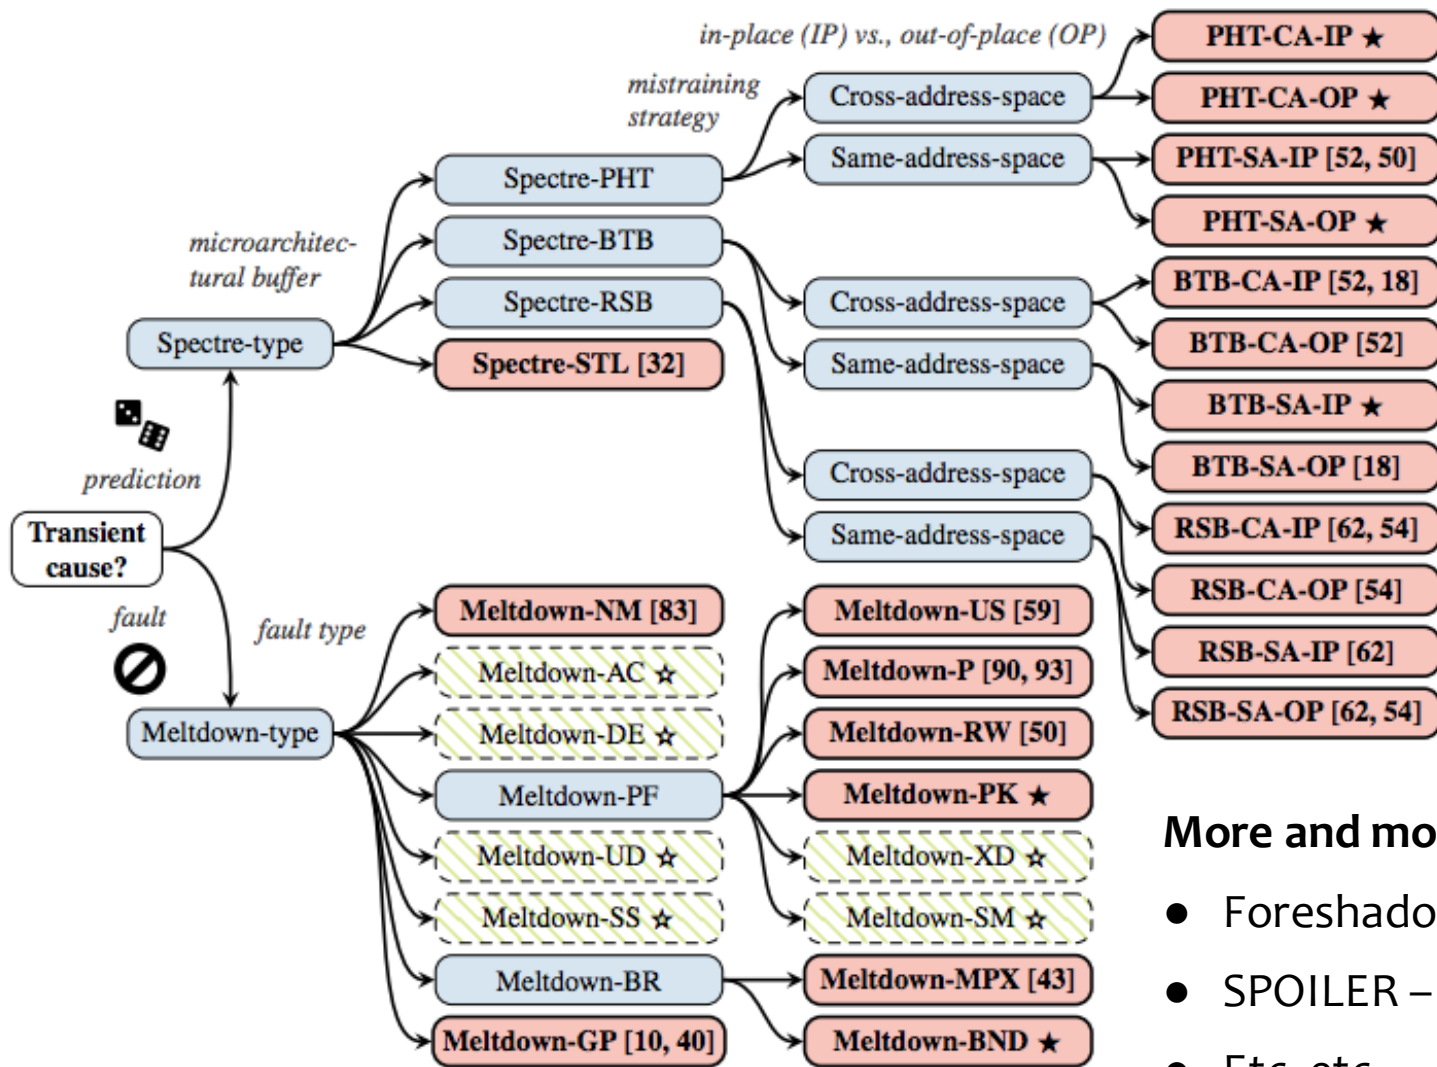

Spectre Attack Sketch

```
if (x < array1_size)
    y = array2[array1[x] * 4096];
```

1. Train branch predictor to follow one branch of conditional.
2. After training, make the followed branch access information that the code should *not* be allowed to access (`secret=array1[x]`).
3. The secret information will affect **which part** of `array2` is loaded into the cache (`array2[secret*4096]`).
4. After the hardware determines that the branch was incorrectly executed, the logic of the program will be rolled back *but* the **cache will still be impacted**.
5. **Time reads to cache** (e.g., Flush+Reload) for accesses to `array2`, to see which cache lines are read more efficiently.

It's A Party

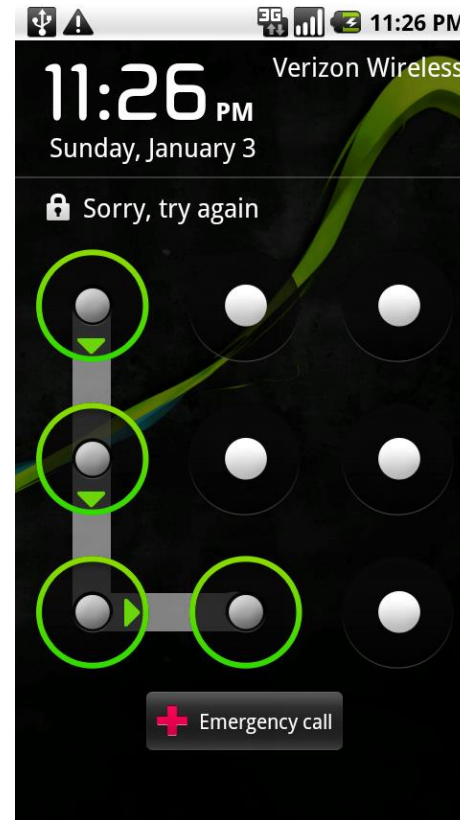

More and more:

- Foreshadow – attacks SGX
- SPOILER – mem dependence
- Etc. etc.

More Examples...

Identifying Web Pages: Electrical Outlets

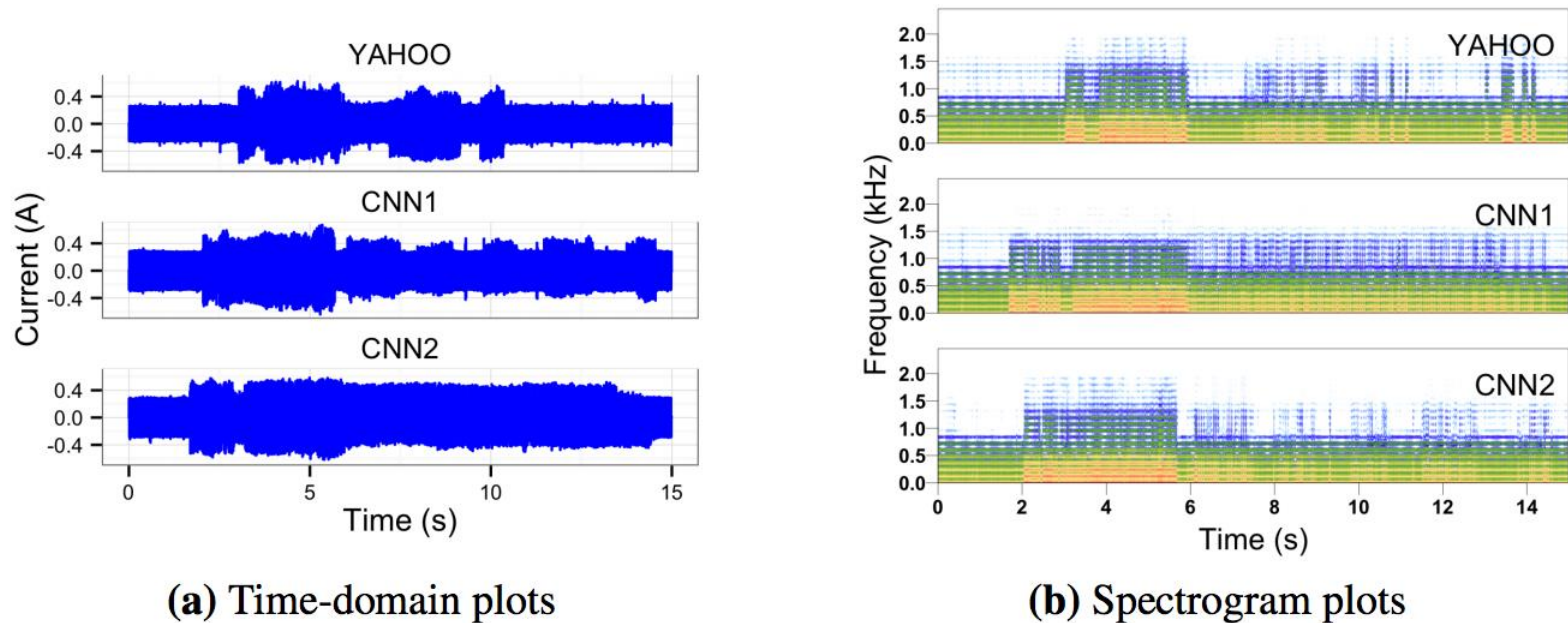

Fig. 1: Time- and frequency-domain plots of several power traces as a MacBook loads two different pages. In the frequency domain, brighter colors represent more energy at a given frequency. Despite the lack of obviously characteristic information in the time domain, the classifier correctly identifies all of the above traces.

Clark et al. “Current Events: Identifying Webpages by Tapping the Electrical Outlet” ESORICS 2013

Powerline Eavesdropping

Figure 1: Frequency spectrogram showing various electrical appliances in the home. Washer cycle on (1) and off (2). CFL lamp turning off briefly (3) and then on (4). Note that the TV's (Sharp 42" LCD) EMI shifts in frequency, which happens as screen content changes.
