SQL Injection

SQL Injection: Basic Idea

A → S

Authentication with Backend DB

```
set UserFound = execute(  
    "SELECT * FROM UserTable WHERE  
    username= ' " & form("user") & " ' AND  
    password= ' " & form("pwd") & " ' " );
```

Username

Password

Sign in ☐ Stay signed in

User supplies username and password, this SQL query checks if user/password combination is in the database

If not UserFound.EOF

Authentication correct

else Fail

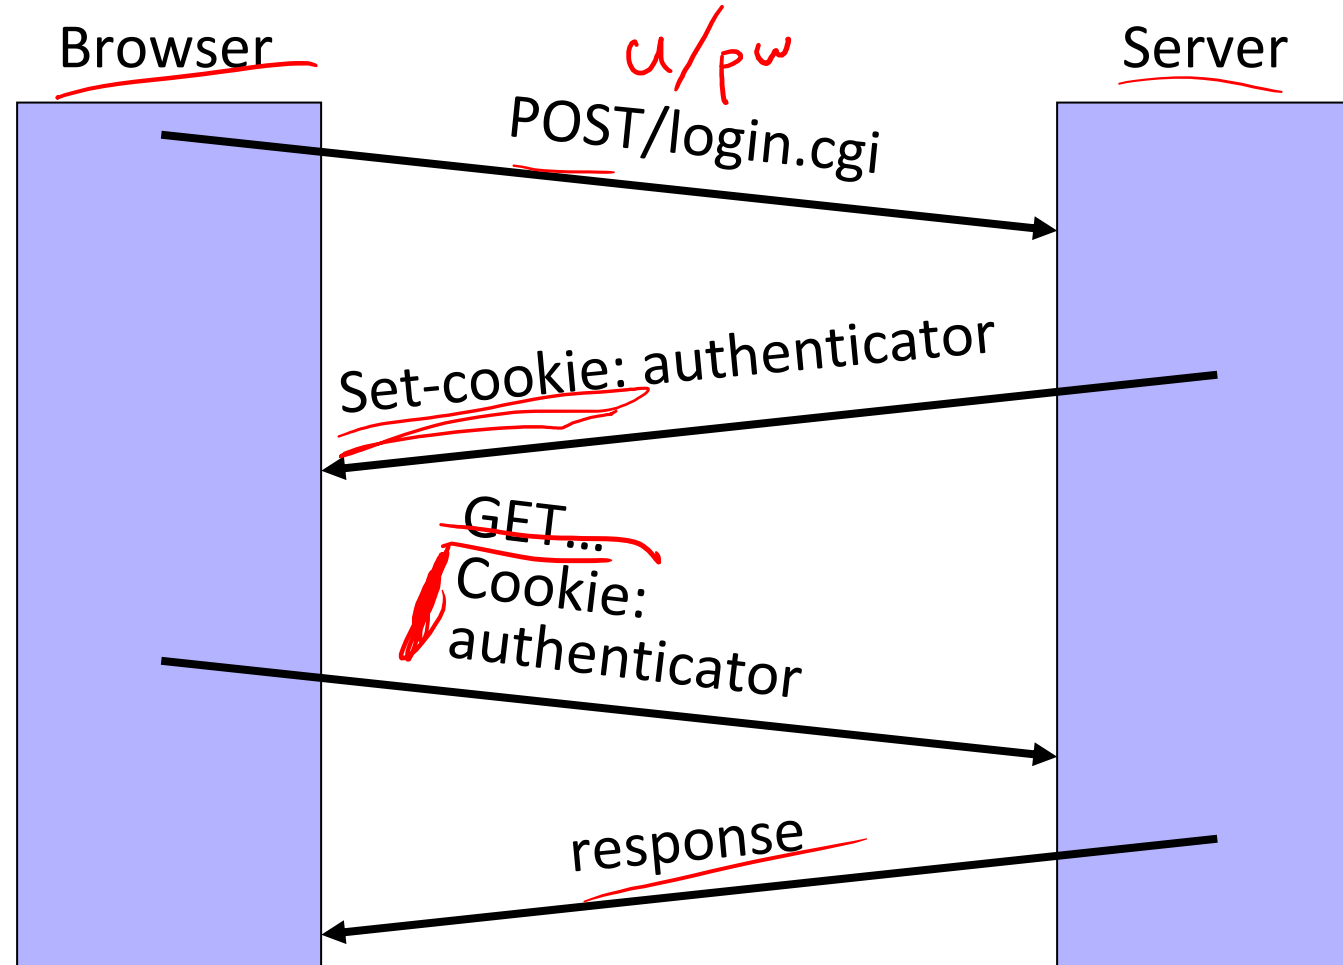

Only true if the result of SQL query is not empty, i.e., user/pwd is in the database

Cross-Site Request Forgery (CSRF/XSRF)

Cookie-Based Authentication Redux

HTTP
[GET
POST]

Browser Sandbox Redux

- Based on the same origin policy (SOP)
- Active content (scripts) can send anywhere!
 - For example, can submit a POST request
 - Some ports inaccessible -- e.g., SMTP (email)
- Can only *read* response from the *same origin*
 - ... but you can do a lot with just sending!

SOP

B → US

Cross-Site Request Forgery

- Users logs into bank.com, forgets to sign off
 - Session cookie remains in browser state
- User then visits a malicious website containing

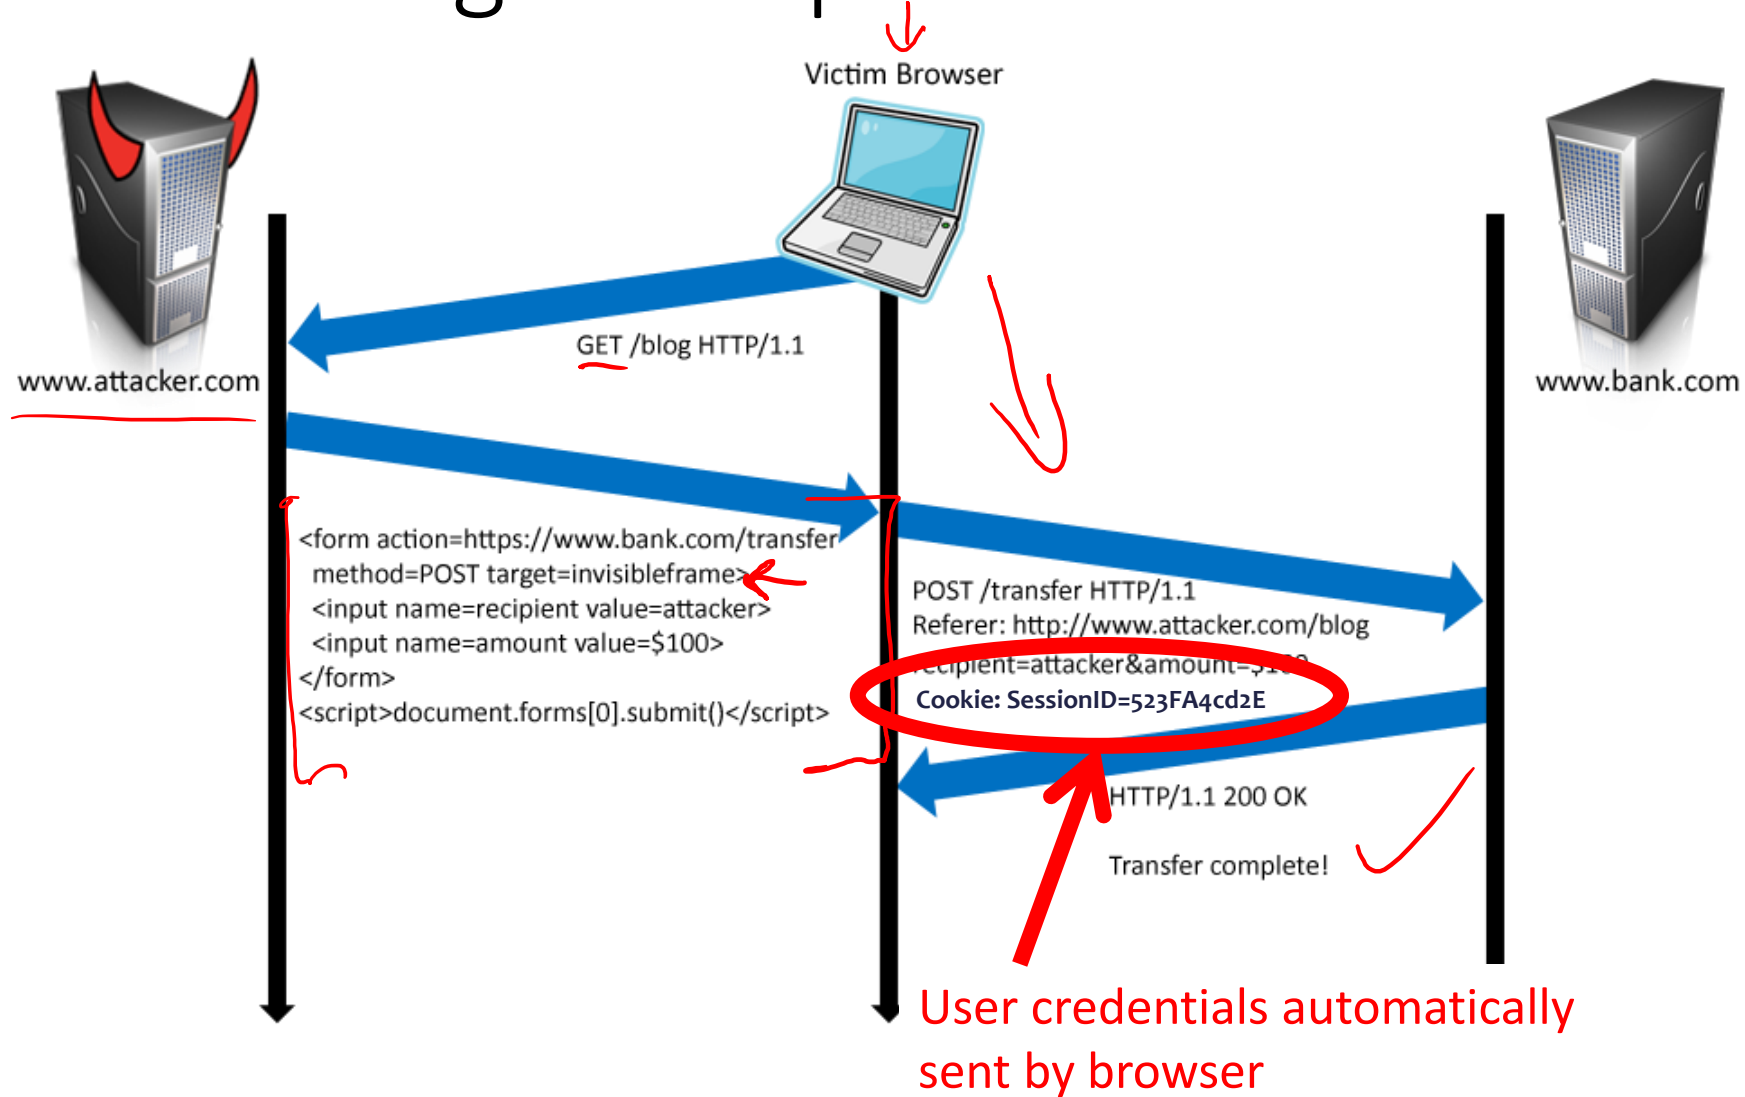

```
<form name=BillPayForm  
action=http://bank.com/BillPay.php>  
<input name=recipient value=badguy> ...  
<script> document.BillPayForm.submit(); </script>
```

POST

viewbalance

- Browser sends cookie, payment request fulfilled!
- Lesson: cookie authentication is not sufficient when side effects can happen

Cookies in Forged Requests

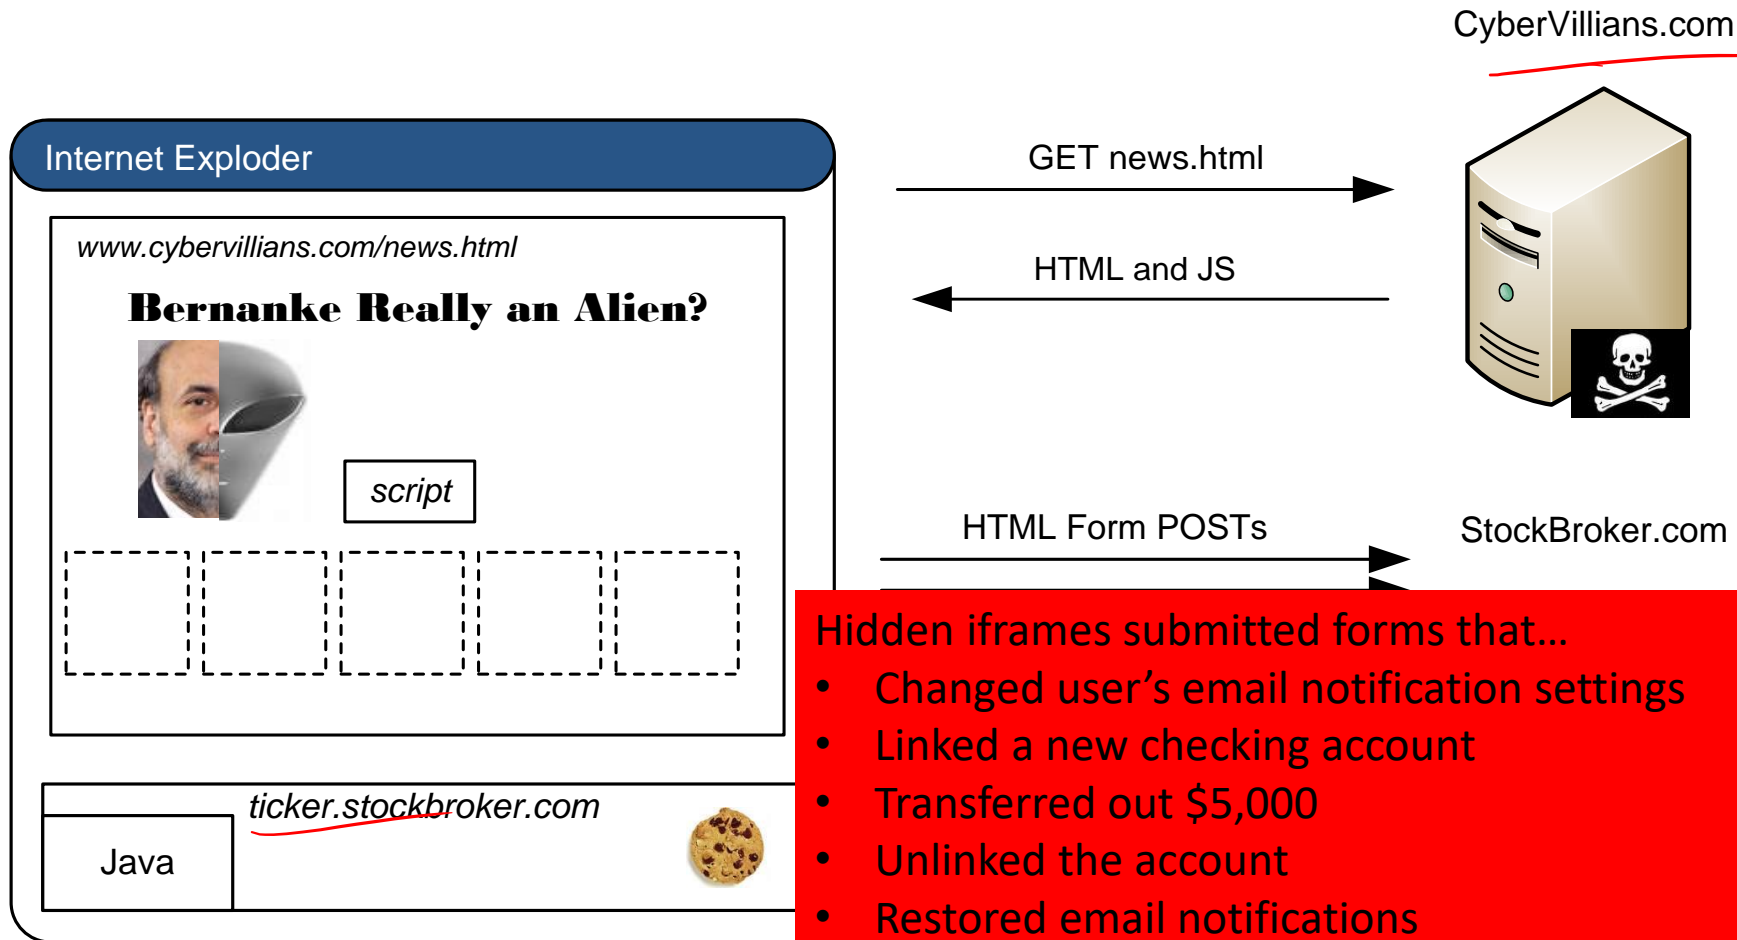

Impact

- Hijack any ongoing session (if no protection)
 - Netflix: change account settings, Gmail: steal contacts, Amazon: one-click purchase
- Reprogram the user's home router ←
- Login to the *attacker's* account ↗
 - Why?

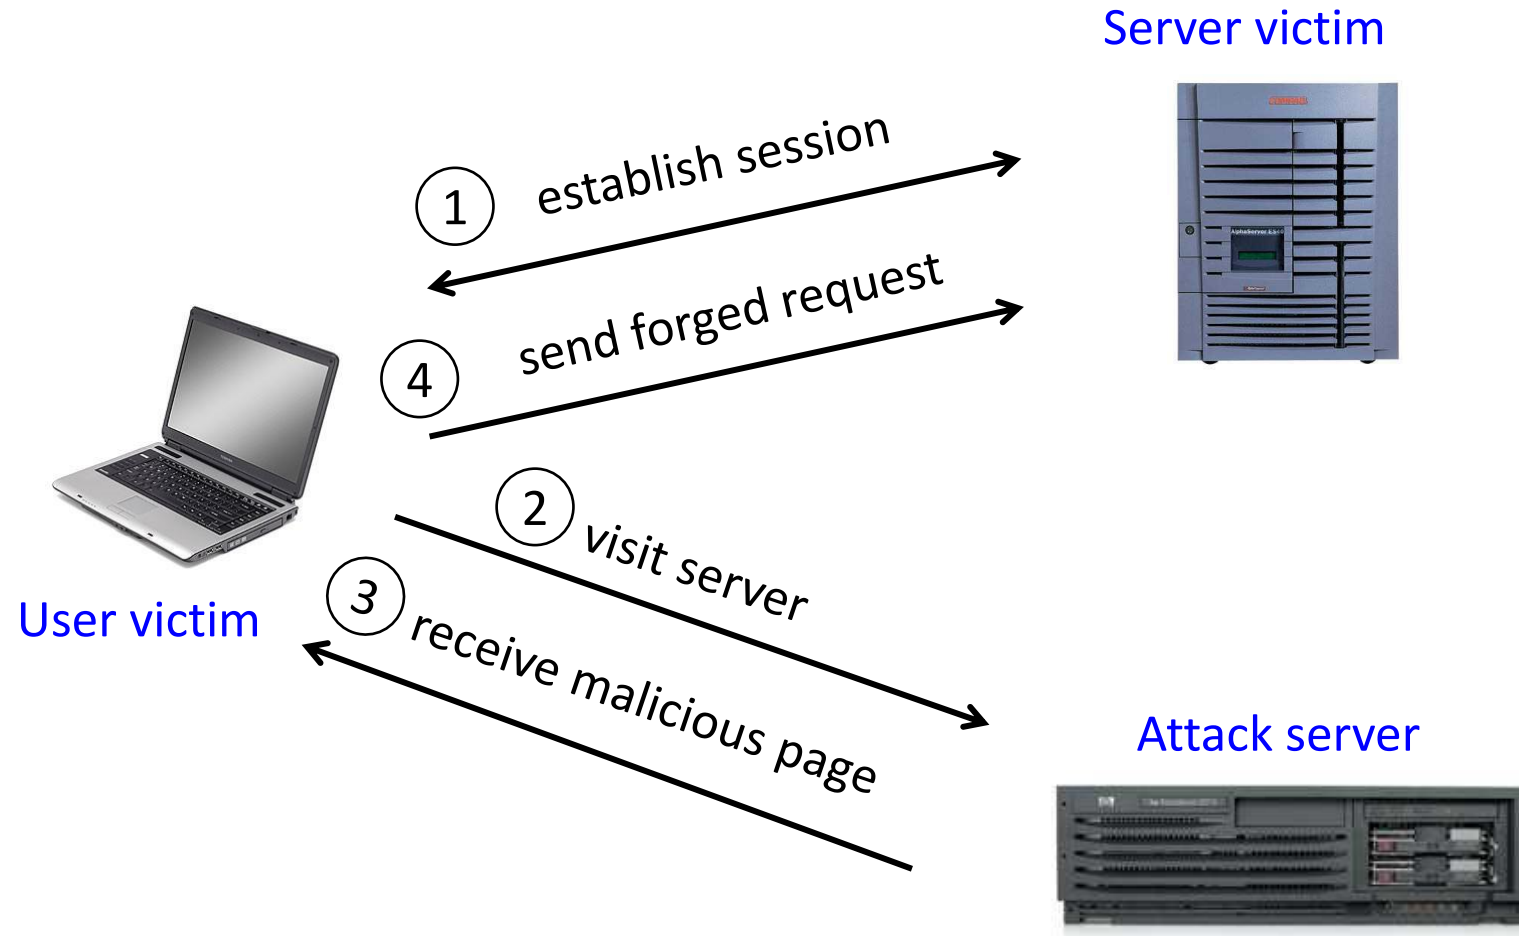

XSRF True Story

[Alex Stamos]

XSRF (aka CSRF): Summary

Q: how long do you stay logged on to Gmail? Financial sites?

Broader View of XSRF

- Abuse of cross-site data export
 - SOP does not control data export
 - Malicious webpage can initiate requests from the user's browser to an honest server
 - Server thinks requests are part of the established session between the browser and the server (automatically sends cookies)

XSRF Defenses

- Secret validation token

```
<input type=hidden value=23a3af01b>
```

- Referer validation

```
Referer:  
http://www.facebook.com/home.php
```

Add Secret Token to Forms

```
<input type=hidden value=23a3af01b>
```

- “Synchronizer Token Pattern”

CSRF Tokens

- Include a **secret challenge token** as a hidden input in forms
 - Token often based on user's session ID
 - Server must verify correctness of token before executing sensitive operations
- Why does this work?
 - **Same-origin policy**: attacker can't read token out of legitimate forms loaded in user's browser, so can't create fake forms with correct token

POST

Referer Validation

Facebook Login

For your security, never enter your Facebook password on sites not located on Facebook.com.

Email:

Password:

☐ Remember me

[Login](#) or [Sign up for Facebook](#)

[Forgot your password?](#)

Referer:

http://www.facebook.com/home.php

Referer:

http://www.evil.com/attack.html

Referer:

- **Lenient** referer checking – header is optional
- **Strict** referer checking – header is required

Why Not Always Strict Checking?

NSA wiki / project tap
cellphones /

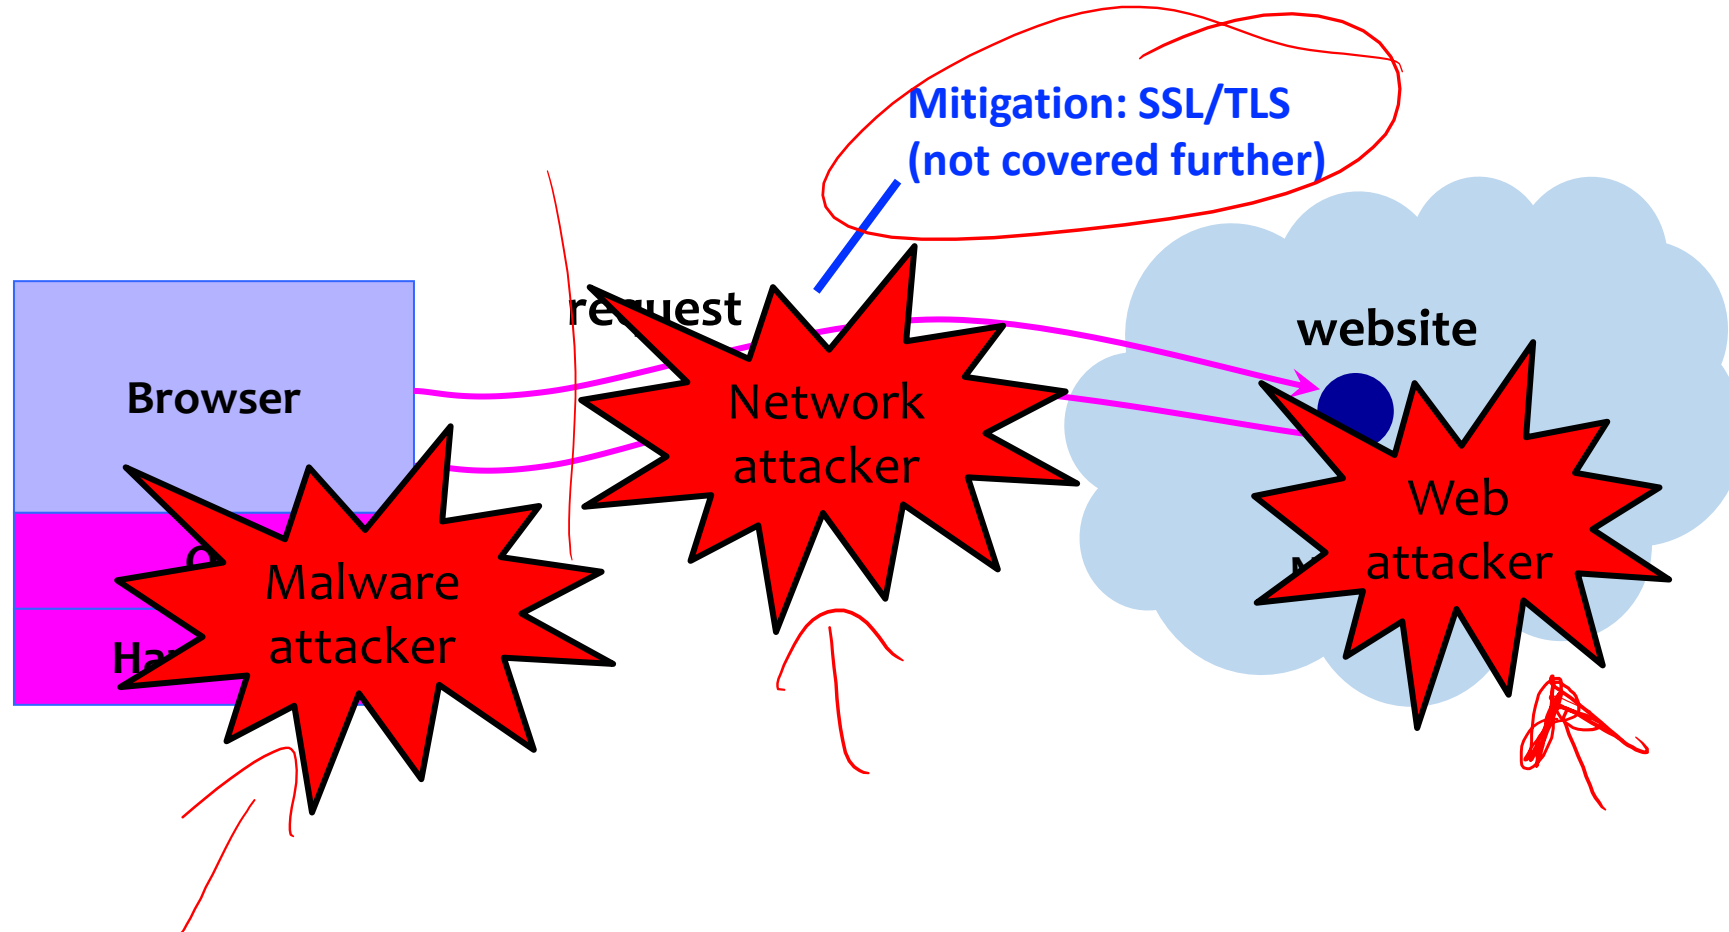

- Why might the referer header be suppressed?
 - Stripped by the organization's network filter
 - Stripped by the local machine
 - Stripped by the browser for HTTPS → HTTP transitions
 - User preference in browser
 - Buggy browser
- Web applications can't afford to block these users
- Many web application frameworks include CSRF defenses today

tokens!

Bonus topic:
Consider the network

Where Does the Attacker Live?

Network attacker

- Lives between you and your destination server

- Person-in-the-middle

- Person-on-the-side

- Passive/active

- Physical/remote

TREVOR PAGLEN

NSA-Tapped Undersea Cables, North Pacific Ocean, 2016

What might they be interested in?

- Eavesdropping  eve
- Making us talk to the wrong server 
- Denial-of-service 
- Corrupting our conversation with a real server 

vs TCP

DNS is *unauthenticated* and over UDP

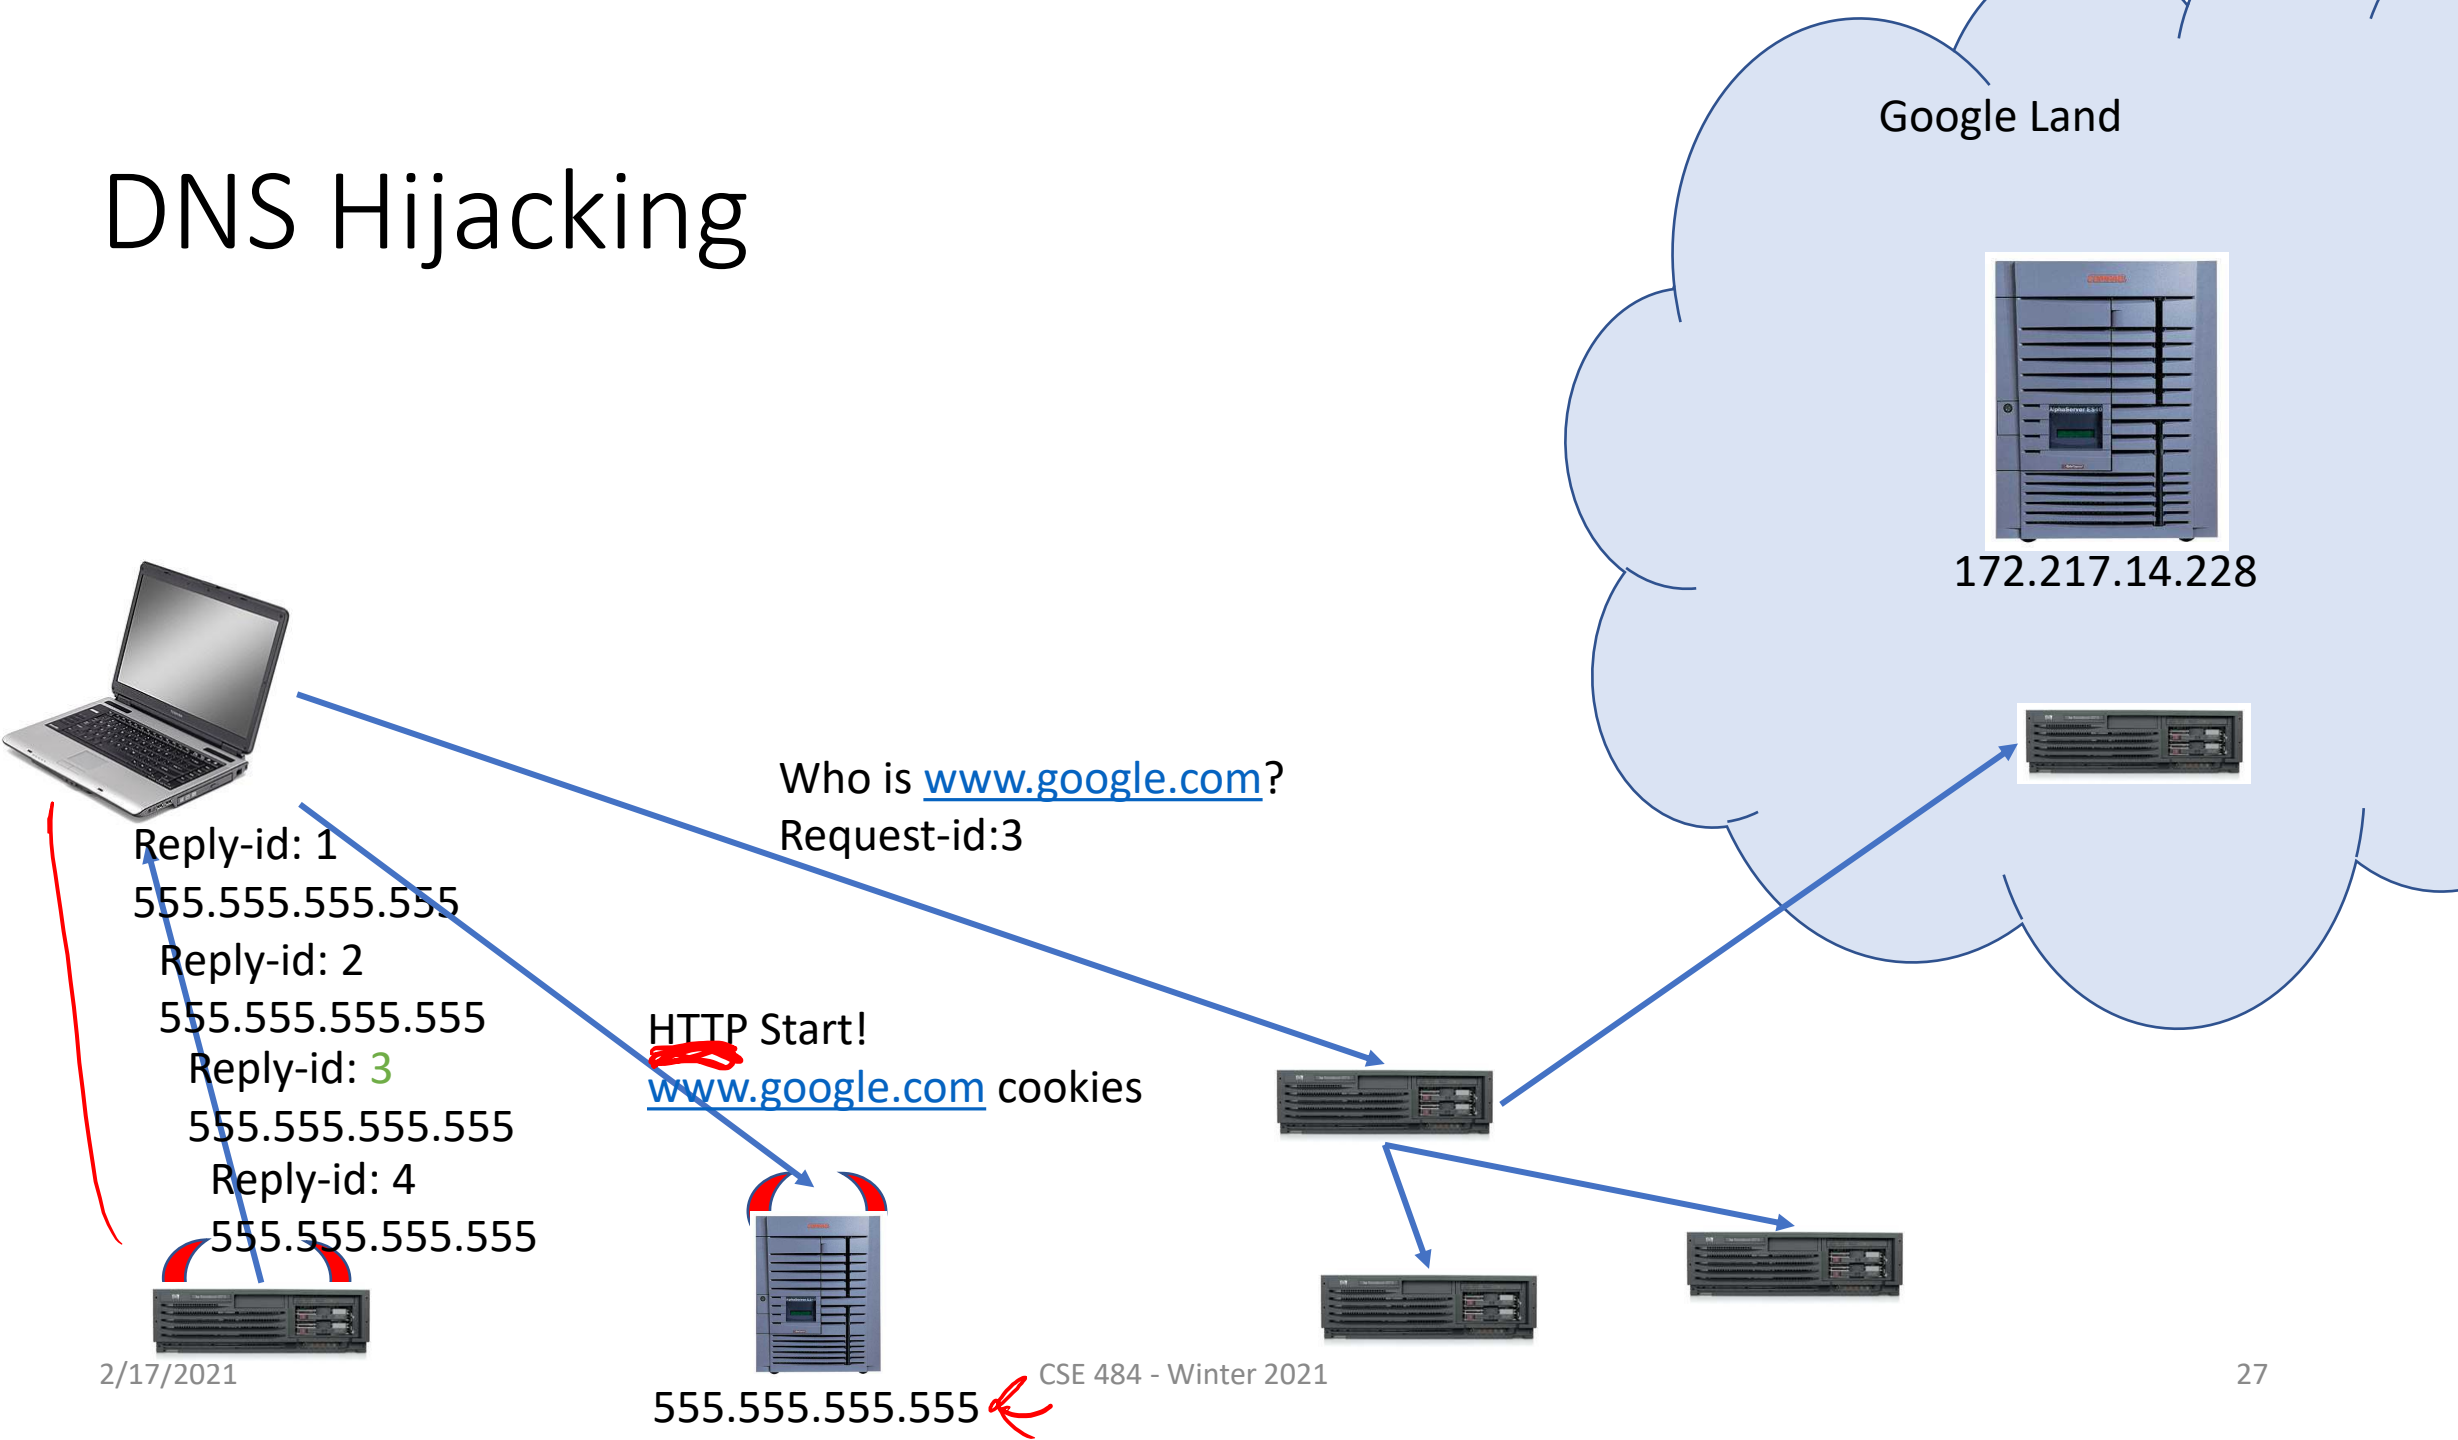

- 16-bit 'request ID'
 - Used to be sequential
 - Now random
- Reply is cleartext and 'simple'

DNS Hijacking

Throwback: Birthday Paradox

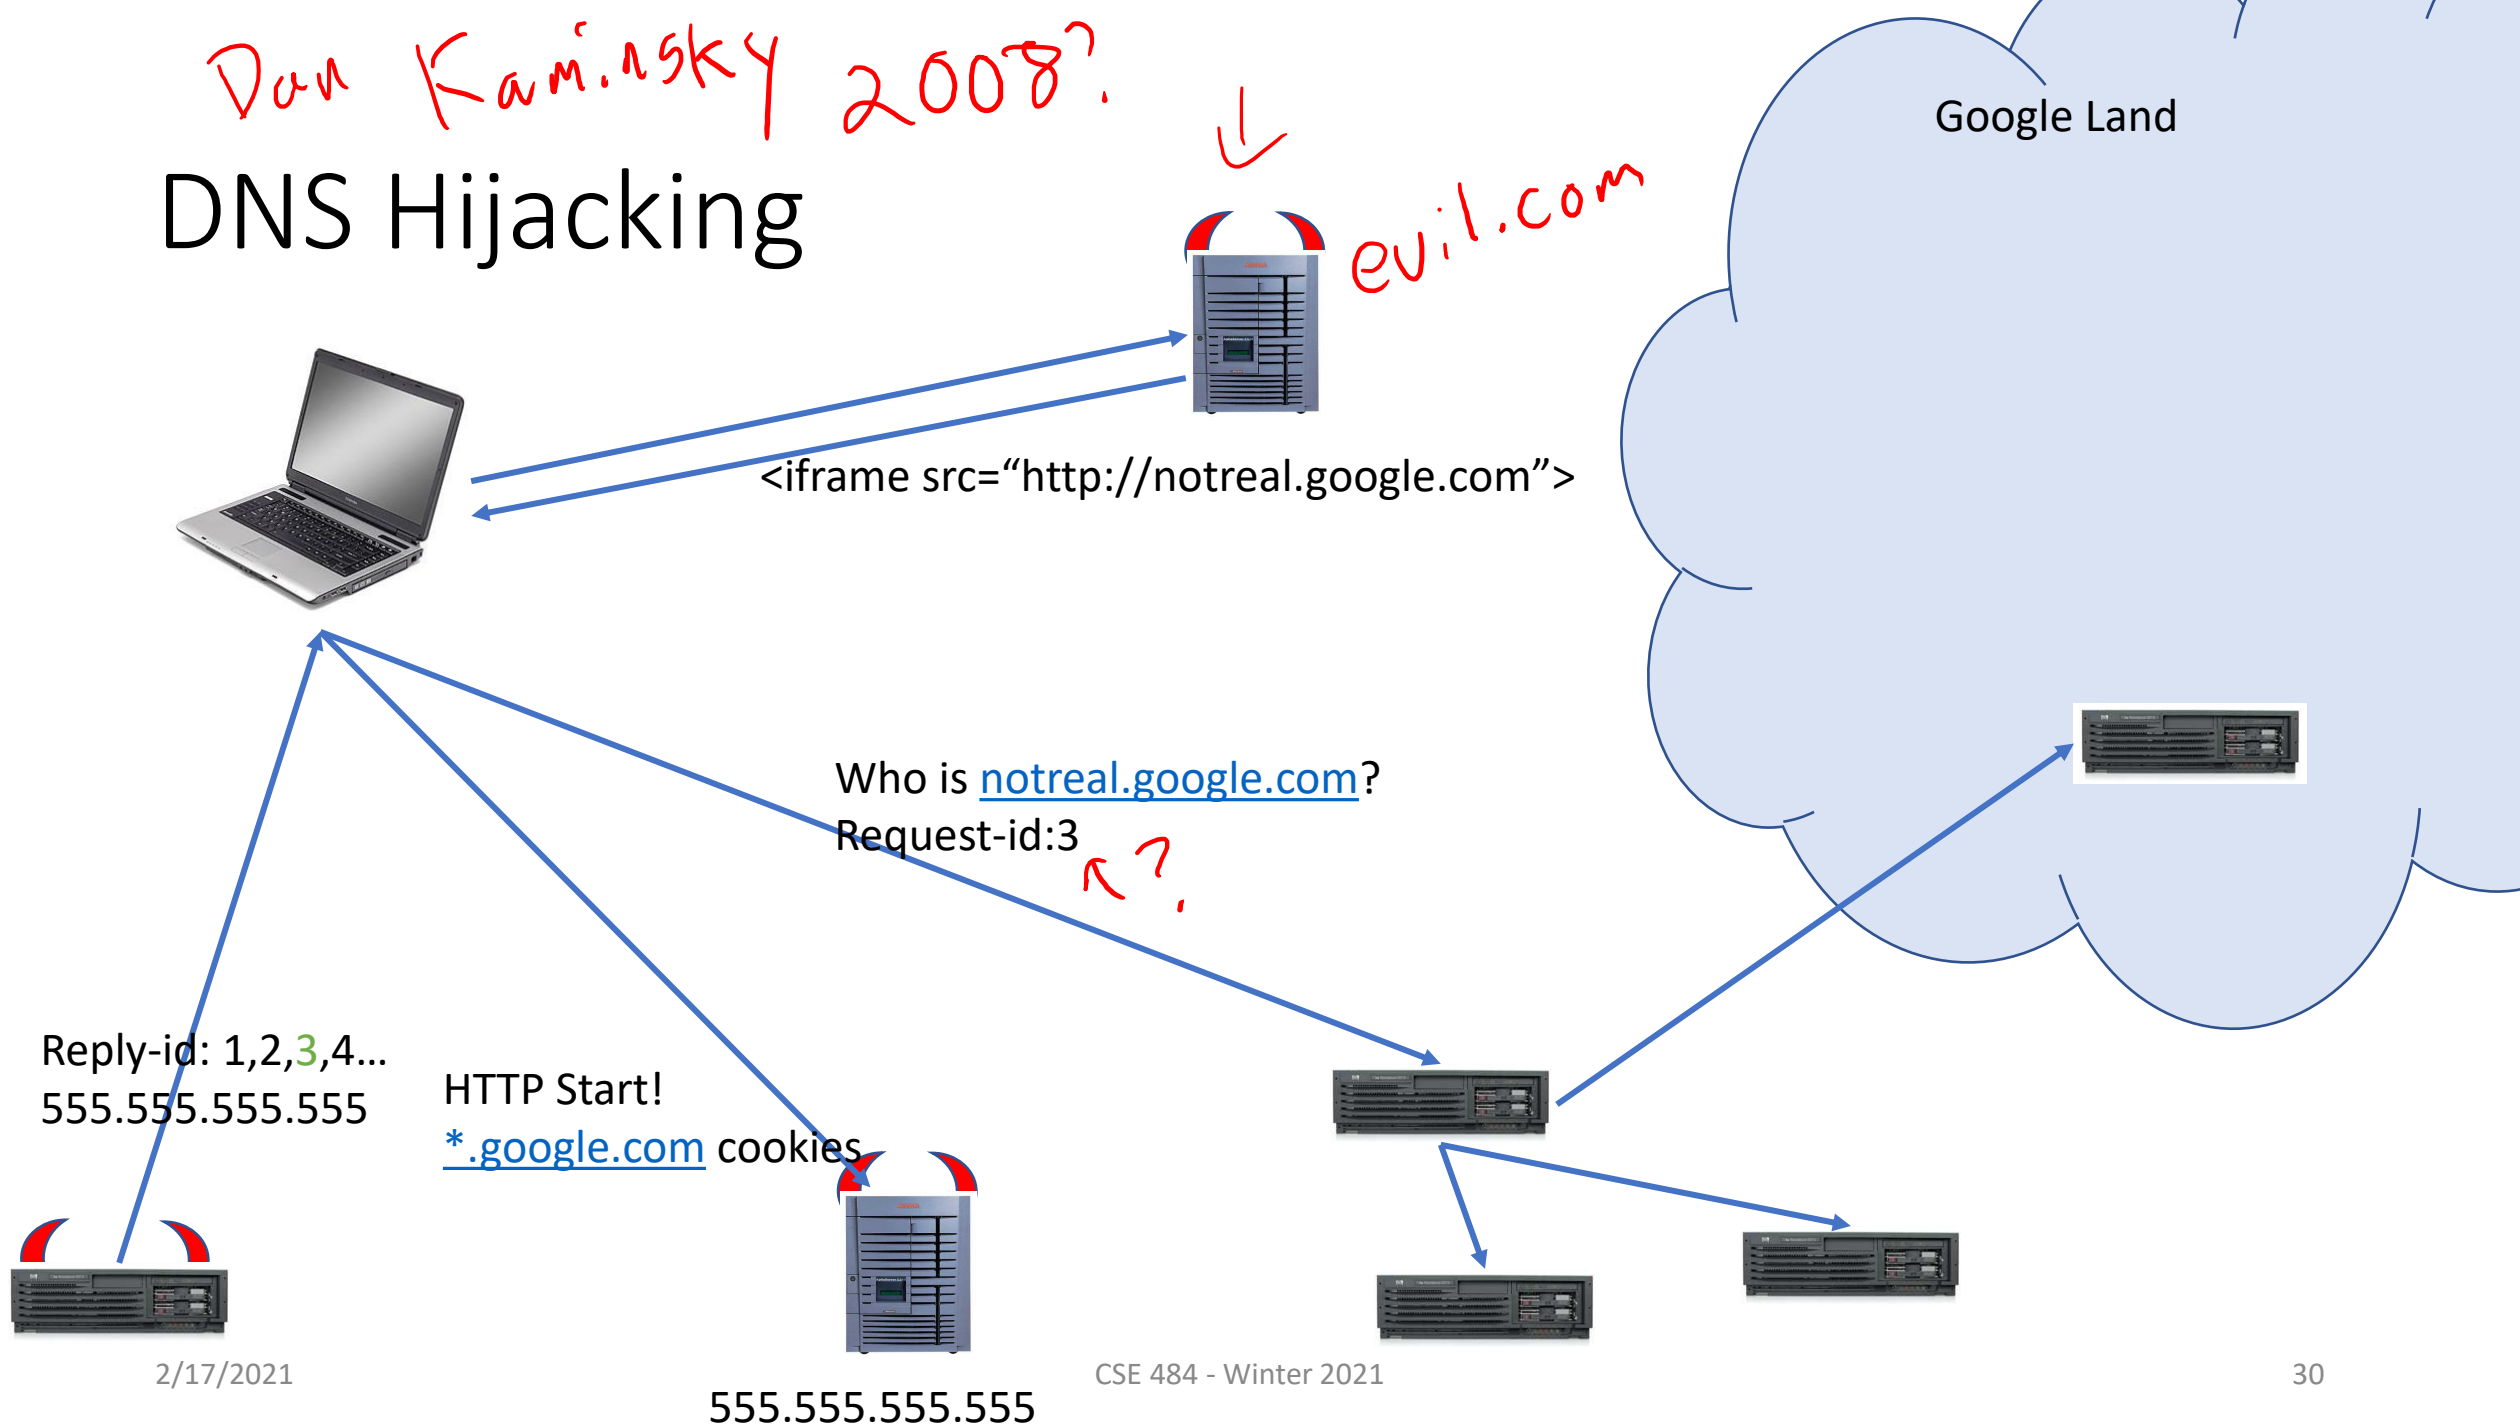

- Are there two people in the first 1/8 of this class that have the same birthday?
 - 365 days in a year (366 some years)
 - Pick one person. To find another person with same birthday would take on the order of $365/2 = 182.5$ people
 - **Expect birthday “collision” with a room of only 23 people.**
 - For simplicity, approximate when we expect a collision as $\text{sqrt}(365)$.
- Why is this important for cryptography?
 - 2^{128} different 128-bit values
 - Pick one value at random. To exhaustively search for this value requires trying on average 2^{127} values.
 - **Expect “collision” after selecting approximately 2^{64} random values.**
 - **64 bits** of security against collision attacks, not 128 bits.

DNS Hijacking Continued

- 16-bit ID: 2^8 for collision (256!)
- How do we get the victim to as for www.google.com?
 - How about “notreal.google.com” instead?

Dan Kaminsky 2008?

DNS Hijacking

The state of DNS

- Randomize:

- Request ID

- **Port number**

- ... hope!
