CSE 484 / CSE M 584: Defenses & Software Security & Buffer Overflows

Winter 2022

Tadayoshi (Yoshi) Kohno yoshi@cs

UW Instruction Team: David Kohlbrenner, Yoshi Kohno, Franziska Roesner. Thanks to Dan Boneh, Dieter Gollmann, Dan Halperin, John Manferdelli, John Mitchell, Vitaly Shmatikov, Bennet Yee, and many others for sample slides and materials ...

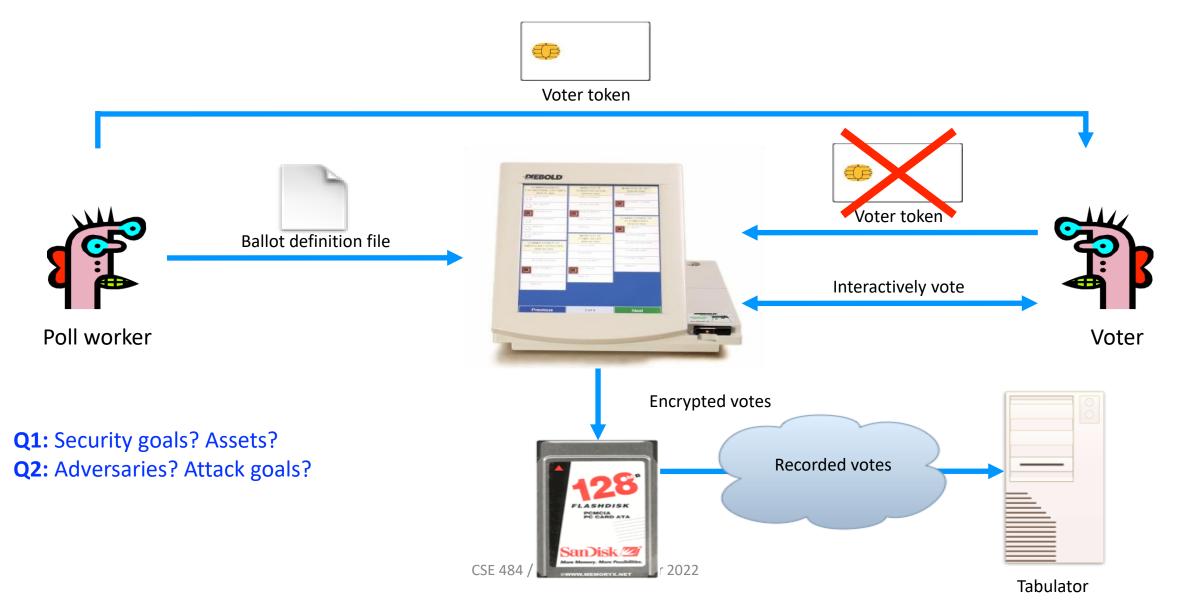

Announcements

- Things Due:
 - Ethics Form: Friday
 - Homework #1: Due next Thursday
 - Research Readings (CSE M 584): Due next Thursday (and every Thursday thereafter)
- Discussion Board:
 - Ideally set up soon

Last time...

- Threat models
 - Assets
 - Adversaries
 - Vulnerabilities
 - Threats
 - Risks

Electronic Voting Machine (~2003)

TOWARDS DEFENSES

CSE 484 / CSE M 584 - Winter 2022

Approaches to Security

- Prevention
 - Stop an attack
- Detection
 - Detect an ongoing or past attack
- Response and Resilience
 - Respond to / recover from attacks
- The threat of a response may be enough to deter some attackers

- Securing a system involves a whole-system view
 - Cryptography
 - Implementation
 - People
 - Physical security
 - Everything in between
- This is because "security is only as strong as the weakest link," and security can fail in many places
 - No reason to attack the strongest part of a system if you can walk right around it.

- Securing a system involves a whole-
 - Cryptography
 - Implementation
 - People
 - Physical security
 - Everything in between

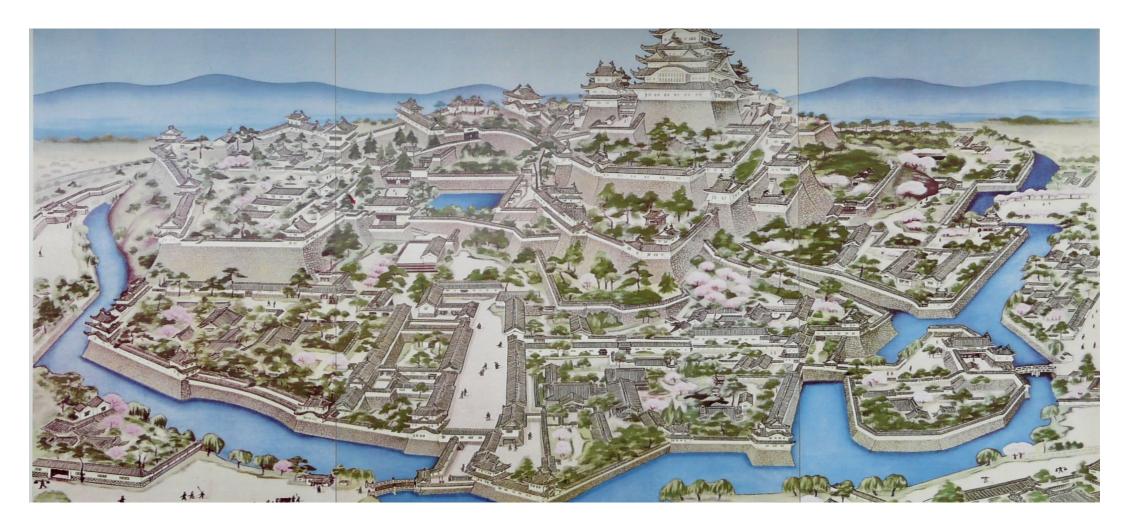

- This is because "security is only as strong as the weakest link," and security can fail in many places
 - No reason to attack the strongest part of a system if you can walk right around it.

Attacker's Asymmetric Advantage

CSE 484 / CSE M 584 - Winter 2022

Attacker's Asymmetric Advantage

- Attacker only needs to win in one place
- Defender's response: Defense in depth

From Policy to Implementation

- After you've figured out what security means to your application, there are still challenges:
 - Requirements bugs and oversights
 - Incorrect or problematic goals
 - Design bugs and oversights
 - Poor use of cryptography
 - Poor sources of randomness
 - ...
 - Implementation bugs and oversights
 - Buffer overflow attacks
 - ...
 - Is the system usable?

Many Participants

- Many parties involved
 - System developers
 - Companies deploying the system
 - The end users
 - The adversaries (possibly one of the above)
- Different parties have different goals
 - System developers and companies may wish to optimize cost
 - End users may desire security, privacy, and usability
 - Related question: Do system developers / companies really understand the needs and values of all their users? Or all stakeholders who might be impacted by the system?
 - The relationship between these goals is quite complex (e.g., will customers choose features or security?) (e.g., are there "non-obvious" stakeholders?)

Better News

- There are a lot of defense mechanisms
 - We'll study some, but by no means all, in this course
- It's important to understand their limitations
 - "If you think cryptography will solve your problem, then you don't understand cryptography... and you don't understand your problem"
 - -- Bruce Schneier

SOFTWARE SECURITY

Bugs, Vulnerabilities, and Exploits

- Bug
 - Not working quite right
- Vulnerability
 - A malfunction that can be used for an adversary's goals
- Exploit
 - The mechanical set of operations to make use of a vulnerability

Adversarial Failures

- Software bugs are bad
 - Consequences can be serious
- Even worse when an intelligent adversary wishes to exploit them!
 - Intelligent adversaries: Force bugs into "worst possible" conditions/states
 - Intelligent adversaries: Pick their targets

Many Types of Vulnerabilities

- Memory corruption (e.g., buffer overflow)
- Type confusion (e.g., implicit cast)
- Input validation/sanitization errors (e.g., Log4j)
- Confused deputy (e.g., CSRF)
- Time-of-check-time-of-use
- Side-channels

Memory Corruption Bugs

- Buffer overflows bugs: <u>Big</u> class of bugs
 - Normal conditions: Can sometimes cause systems to fail
 - Adversarial conditions: Attacker able to violate security of your system (control, obtain private information, ...)
- Stack, Heap both possibilities

BUFFER OVERFLOWS

A Bit of History: Morris Worm

- Worm was released in 1988 by Robert Morris
 - Graduate student at Cornell, son of NSA chief scientist
 - Convicted under Computer Fraud and Abuse Act,
 - 3 years probation and 400 hours of community service
- Worm was intended to propagate slowly and harmlessly measure the size of the Internet
- Due to a coding error, it created new copies as fast as it could and overloaded infected machines
- \$10-100M worth of damage (in 1988)

Morris Worm and Buffer Overflow

- One of the worm's propagation techniques was a buffer overflow attack against a vulnerable version of fingerd on VAX systems
 - By sending special string to finger daemon, worm caused it to execute code creating a new worm copy

Buffer overflows remain a common source of vulnerabilities and exploits today! (Especially in embedded systems.)

Aside: Famous Internet Worms

- Morris worm (1988): overflow in fingerd
 - 6,000 machines infected
- CodeRed (2001): overflow in MS-IIS server
 - 300,000 machines infected in 14 hours
- SQL Slammer (2003): overflow in MS-SQL server
 - 75,000 machines infected in **10 minutes** (!!)
- Sasser (2005): overflow in Windows LSASS
 - Around 500,000 machines infected

... And More

- Conficker (2008-09): overflow in Windows RPC
 - Around 10 million machines infected (estimates vary)
- Stuxnet (2009-10): several zero-day overflows + same Windows RPC overflow as Conficker
 - Windows print spooler service
 - Windows LNK shortcut display
 - Windows task scheduler
- Flame (2010-12): same print spooler and LNK overflows as Stuxnet
 - Targeted cyperespionage virus
- These days, worms are uncommon

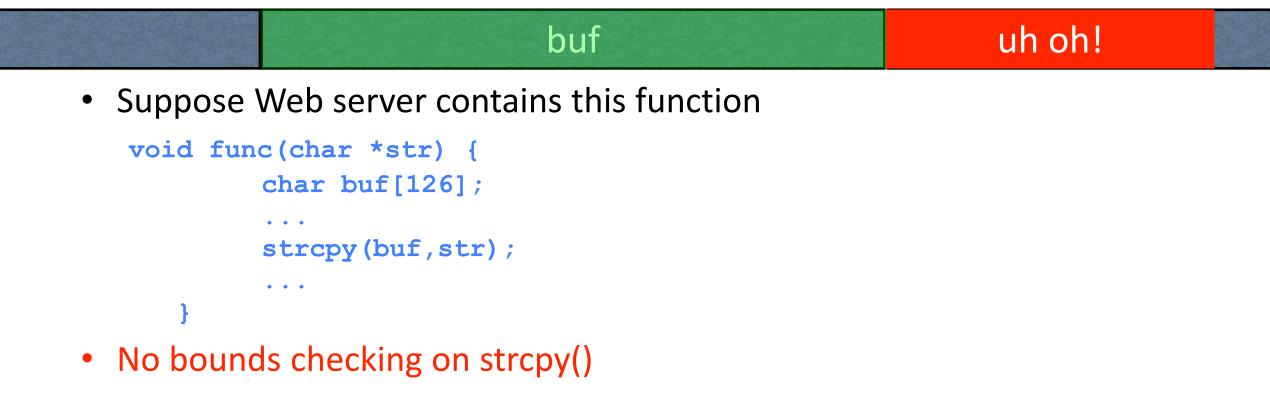

... And More

- Embedded systems
 - E.g., UW automotive security work
- Formative and foundational for software security

Attacks on Memory Buffers

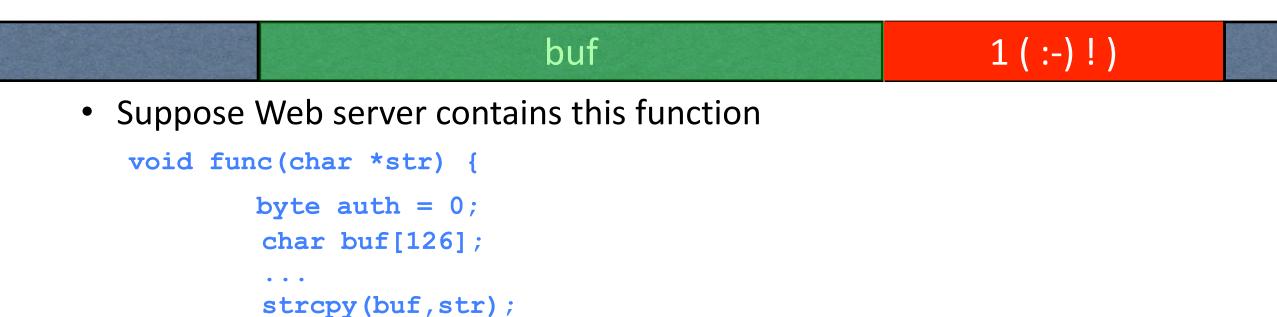

- Buffer is a pre-defined data storage area inside computer memory (stack or heap)
- Typical situation:
 - A function takes some input that it writes into a pre-allocated buffer.
 - The developer forgets to check that the size of the input isn't larger than the size of the buffer.
 - Uh oh.
 - "Normal" bad input: crash
 - "Adversarial" bad input : take control of execution

Stack Buffers

- If str is longer than 126 bytes
 - Program may crash
 - Attacker may change program behavior

Example: Changing Flags

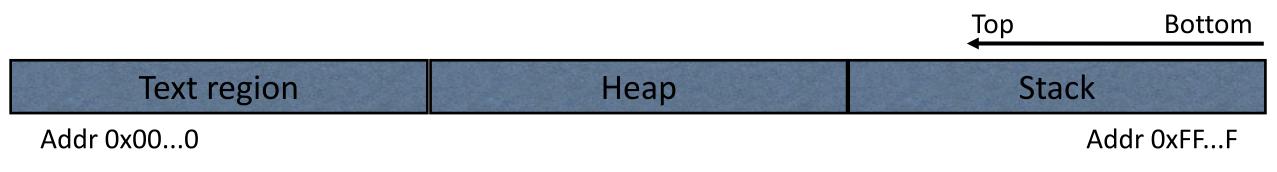

- Authenticated variable non-zero when user has extra privileges
- Morris worm also overflowed a buffer to overwrite an authenticated flag in fingerd

• • •

Memory Layout

- Text region: Executable code of the program
- Heap: Dynamically allocated data
- Stack: Local variables, function return addresses; grows and shrinks as functions are called and return

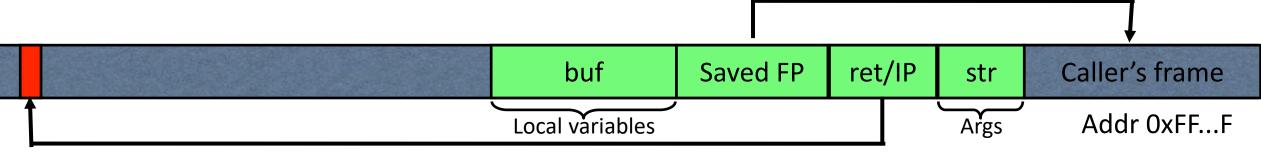

Stack Buffers

• Suppose Web server contains this function:

• When this function is invoked, a new frame (activation record) is pushed onto the stack.

Execute code at this address after func() finishes

What if Buffer is Overstuffed?

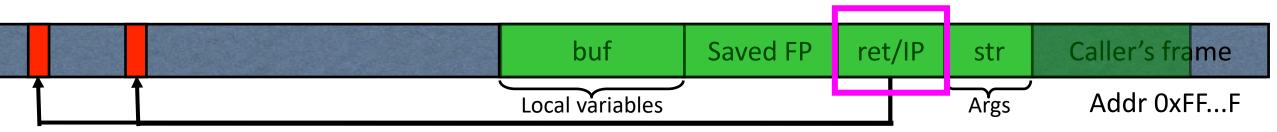

• Memory pointed to by str is copied onto stack...

```
void func(char *str) {
    char buf[126];
    strcpy(buf,str);
}
```

strcpy does NOT check whether the string at *str contains fewer than 126 characters

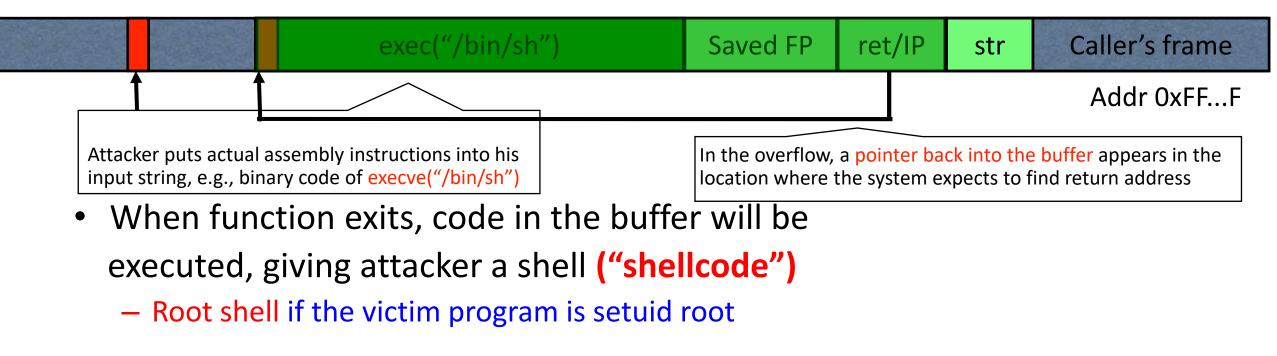

• If a string longer than 126 bytes is copied into buffer, it will overwrite adjacent stack locations.

This will be interpreted as return address!

Executing Attack Code

- Suppose buffer contains attacker-created string
 - For example, str points to a string received from the network as the URL

Buffer Overflows Can Be Tricky...

- Overflow portion of the buffer must contain correct address of attack code in the RET position
 - The value in the RET position must point to the beginning of attack assembly code in the buffer
 - Otherwise application will (probably) crash with segfault
 - Attacker must correctly guess in which stack position his/her buffer will be when the function is called

Problem: No Bounds Checking

- strcpy does <u>not</u> check input size
 - strcpy(buf, str) simply copies memory contents into buf starting from *str until "\0" is encountered, ignoring the size of area allocated to buf
- Many C library functions are unsafe
 - strcpy(char *dest, const char *src)
 - strcat(char *dest, const char *src)
 - gets(char *s)
 - scanf(const char *format, ...)
 - printf(const char *format, ...)

Does Bounds Checking Help?

- strncpy(char *dest, const char *src, size_t n)
 - If strncpy is used instead of strcpy, no more than n characters will be copied from *src to *dest
 - Programmer has to supply the right value of n
- Potential overflow in htpasswd.c (Apache 1.3):

```
strcpy(record,user);
strcat(record,":");
strcat(record,cpw);
```

Copies username ("user") into buffer ("record"),
 then appends ":" and hashed password ("cpw")

• Published fix:

```
strncpy(record,user,MAX_STRING_LEN-1);
strcat(record,":")
strncat(record,cpw,MAX_STRING_LEN-1);
```

Breakout Activity

Canvas -> Quizzes

What About This?

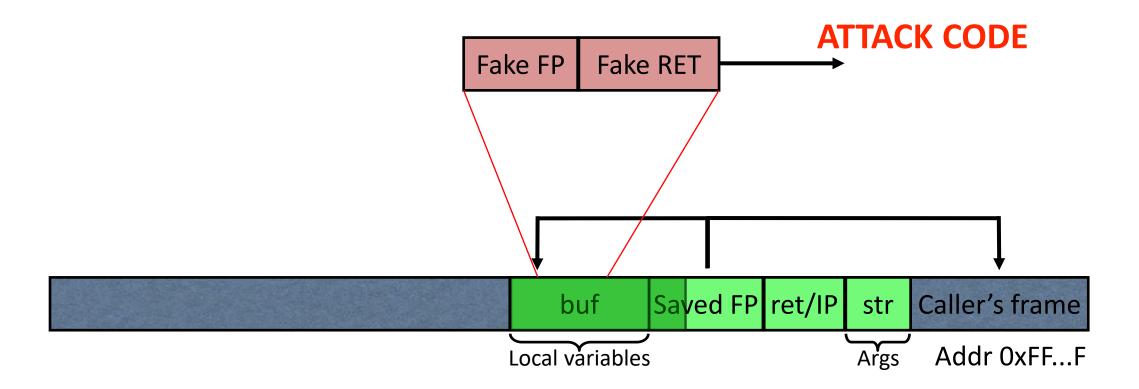

Home-brewed range-checking string copy

```
void mycopy(char *input) {
    char buffer[512]; int i;
    for (i=0; i<=512; i++)
        buffer[i] = input[i];
    }
    void main(int argc, char *argv[]) {
        if (argc==2)
            mycopy(argv[1]);
    }
</pre>
```

Breakout Activity

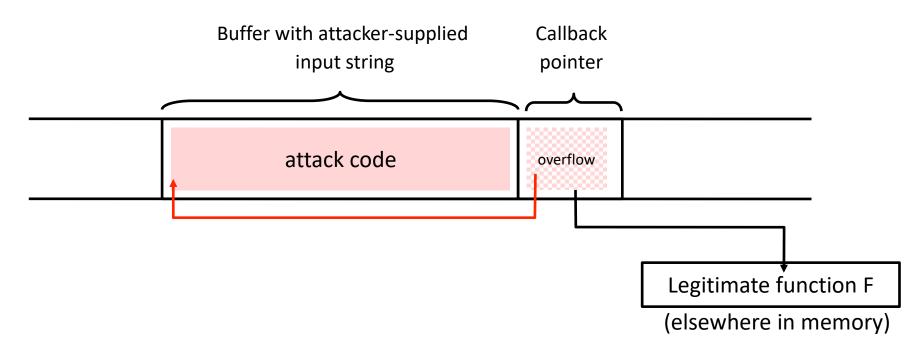

Canvas -> Quizzes

Frame Pointer Overflow

Another Variant: Function Pointer Overflow

• C uses function pointers for callbacks: if pointer to F is stored in memory location P, then one can call F as (*P)(...)

Other Overflow Targets

- Format strings in C
 - We'll walk through this later
- Heap management structures used by malloc()
 - More details in section
 - Techniques have changed wildly over time

• These are all attacks you can look forward to in Lab #1 😳
