

CSE 484/M584: Computer Security (and Privacy)

Spring 2025

David Kohlbrenner
dkohlbre@cs

UW Instruction Team: David Kohlbrenner, Yoshi Kohno, Franziska Roesner, Nirvan Tyagi. Thanks to Dan Boneh, Dieter Gollmann, Dan Halperin, John Manferdelli, John Mitchell, Vitaly Shmatikov, Bennet Yee, and many others for sample slides and materials

Admin

- Lab 3 Weblab due Wednesday
- When helping other students on Ed, make sure you are helping them get unstuck or think about the problem differently, not posting an answer.

Authentication

Basic Problem

How do you prove to someone that
you are who you claim to be?

Any system with access control must solve this problem.

A slightly more fundamental question

- What are we trying to prove?

Many Ways to Prove Who You Are

- “Something you know”
 - Passwords
 - Answers to questions that only you know
- “Something you have”
 - Secure tokens, mobile devices
- “Something you are”
 - Biometrics

Passwords are a classic attack vector

- 2025: 80% of basic Web Application attacks used stolen creds
 - 56% used brute forcing of weak creds
- 2025: ~15% of network intrusions used some sort of stolen/weak credentials
 - In 2022, was 50%!
- Source: Verizon Data Breach Investigations Report
 - <https://www.verizon.com/business/resources/reports/dbir/#archive>
 - Lots of interesting data here.

Passwords are a classic attack vector

- First step after any successful intrusion: search for credentials
 - Install keyloggers/etc to capture more.
- Second step: run cracking tools on password files
 - Cracking needed because modern systems usually do not store passwords in the clear

UNIX-Style Passwords

- How should we store passwords on a server?

- In cleartext?
- Encrypted?
- Hashed?

Gradescope!

- What is a benefit of storing passwords *encrypted*?
- What is a benefit of storing passwords *hashed*?

Password Hashing

- Instead of user password, store $H(\text{password})$
- When user enters password, compute its hash and compare with entry in password file
 - System does not store actual passwords!
 - System itself can't easily go from hash to password
 - Which would be possible if the passwords were encrypted
- Hash function H must have some properties
 - **One-way**: given $H(\text{password})$, hard to find password
 - No known algorithm better than trial and error
 - “Slow” to compute

UNIX Password System

- Approach: Hash passwords
- Problem: passwords are not truly random
 - With 52 upper- and lower-case letters, 10 digits and 32 punctuation symbols, there are 94^8 == 6 quadrillion possible 8-character passwords ($\sim 2^{52}$)
 - **BUT:** Humans like to use dictionary words, human and pet names == 1 million common passwords

Dictionary Attack

- **Dictionary attack** is possible because many passwords come from a small dictionary
 - Attacker can pre-compute $H(\text{word})$ for every word in the dictionary – this only needs to be done once!
 - This is an offline attack
 - Once password file is obtained, cracking is instantaneous
 - Sophisticated password guessing tools are available
 - Take into account freq. of letters, password patterns, etc.

Salt

- Users with the same password have different entries in the password file
- Offline dictionary attack becomes much harder

Advantages of Salting

- Without salt, attacker can pre-compute hashes of all dictionary words once for all password entries
 - Same hash function on all UNIX machines
 - Identical passwords hash to identical values; one table of hash values can be used for all password files
- With salt, attacker must compute hashes of all dictionary words once for each password entry
 - With 12-bit random salt, same password can hash to 2^{12} different hash values
 - Attacker must try all dictionary words **for each salt value** in the password file
- Pepper: Secret salt (not stored in password file)

Other Password Security Risks

- Keystroke loggers
 - Hardware
 - Software (spyware)
- Shoulder surfing
- Same password at multiple sites
- Broken implementations
 - E.g. TENEX timing attack
- Social engineering

Other Issues

- Usability
 - Hard-to-remember passwords?
 - Carry a physical object all the time?
- Denial of service
 - Attacker tries to authenticate as you, account locked after three failures

Default Passwords

- Examples from Mitnick's "Art of Intrusion"
 - U.S. District Courthouse server: "public" / "public"
 - NY Times employee database: pwd = last 4 SSN digits
- Mirai IoT botnet
 - Weak and default passwords on routers and other devices

Weak Passwords

- RockYou hack
 - “Social gaming” company
 - Database with 32 million user passwords from partner social networks
 - Passwords stored in the clear
 - December 2009: entire database hacked using an **SQL injection attack** and posted on the Internet
 - One of many such examples!

Weak Passwords

- RockYou hack

- “ Password Popularity – Top 20

- D
 - p
 - D
 - p

Rank	Password	Number of Users with Password (absolute)
1	123456	290731
2	12345	79078
3	123456789	76790
4	Password	61958
5	iloveyou	51622
6	princess	35231
7	rockyou	22588
8	1234567	21726
9	12345678	20553
10	abc123	17542

Rank	Password	Number of Users with Password (absolute)
11	Nicole	17168
12	Daniel	16409
13	babygirl	16094
14	monkey	15294
15	Jessica	15162
16	Lovely	14950
17	michael	14898
18	Ashley	14329
19	654321	13984
20	Qwerty	13856

Aside: Ethics of studying password breaches

- Is there a risk to using stolen password databases?
- Who might this hurt?
- Is the payoff worth it?

Password Policies

- Old recommendation:
 - 7 or 8 characters, at least 3 out of {digits, upper-case, lower-case, non-alphanumeric}, no dictionary words, change every 4 months, password may not be similar to previous 12 passwords...

Password Policies

- Old recommendation:
 - 7 or 8 characters, at least 3 out of {digits, upper-case, lower-case, non-alphanumeric}, no dictionary words, change every 4 months, password may not be similar to previous 12 passwords...
- **But** ... results in frustrated users and less security
 - Burdens of devising, learning, forgetting passwords
 - Users construct passwords insecurely, write them down
 - Can't use their favorite password construction techniques (small changes to old passwords, etc.)
 - Heavy password re-use across systems
 - (Password managers can help)

“New” (2017) NIST Guidelines 😊

- Remove requirement to periodically change passwords
- Screen for commonly used passwords
- Allow copy-paste into password fields
 - But concern: what apps have access to clipboard?
- Allow but don't require arbitrary special characters
- Etc.

<https://pages.nist.gov/800-63-3/sp800-63b.html>

Improving(?) Passwords

- Add biometrics
 - For example, keystroke dynamics or voiceprint
- Graphical passwords
 - Goal: easier to remember? no need to write down?
- Password managers
 - Examples: LastPass, KeePass, built into browsers
 - Can have security vulnerabilities...
- Two-factor authentication
 - Leverage phone (or other device) for authentication

Password managers

- Generation
 - Secure generation of random passwords
- Management
 - Allows for password-per-account
- Safety?
 - Single point of failure
 - Vulnerability?
 - Phishing?

Multi-Factor Authentication

1. Sign in with your Google Account

Email:
ex: pat@example.com

Password:

☒ Stay signed in

[Can't access your account?](#)

2. Google accounts

Enter verification code

To verify your identity on this computer, enter the verification code generated by your mobile application.

Enter code:

☒ Remember verification for this computer for 30 days.

[Other ways to get a verification code »](#)

Google Authenticator

Turn on Login Approvals

What is Login Approvals?

Login Approvals is a security feature that requires you to enter a code that we text to your phone when you log in from an unrecognized computer. You can enable this feature in a few simple steps.

If you ever lose access to your phone, you can always return to a previously-recognized computer to regain access to your account.

Note: You'll need to have your mobile phone with you to complete this process.

Secondary Factors Do Help!

Account takeover prevention rates, by challenge type

Both device- and knowledge-based challenges help thwart automated bots, while device-based challenges help thwart phishing and even targeted attacks.

Why does hardware 2FA work?

- We need to stop the user *who believe they are logging in* from letting the attacker in.
- Consider:
 - User goes to `attacker[.]com/googlelogin.php`
 - User *tries to log in*
 - How will SMS codes stop the attacker?
 - How will a token that understands origins stop the attacker?

Hardware 2FA tokens (U2F/FIDO)

Graphical Passwords

- Many variants... one example: Passfaces
 - Assumption: easy to recall faces

Graphical Passwords

- Another variant: draw on the image (Windows 8)

- Problem: users choose predictable points/lines

Unlock Patterns

- Problems:
 - Predictable patterns (familiar pattern by now)
 - Smear patterns
 - Side channels: apps can use accelerometer and gyroscope to extract pattern!

What About Biometrics?

- Authentication: **What you are**
- Unique identifying characteristics to authenticate user or create credentials
 - Biological and physiological: Fingerprints, iris scan
 - Behaviors characteristics - how perform actions: Handwriting, typing, gait
- Advantages:
 - Nothing to remember
 - Passive
 - Can't share (generally)
 - With perfect accuracy, could be fairly unique

What are reasons to use/*not* use biometrics?

Issues with Biometrics

- Private, but not secret
 - Maybe encoded on the back of an ID card?
 - Maybe encoded on your glass, door handle, ...
 - Sharing between multiple systems?
- Revocation is difficult (impossible?)
 - Sorry, your iris has been compromised, please create a new one...
- Physically identifying
 - Soda machine to cross-reference fingerprint with DMV?
- Birthday paradox
 - With false accept rate of 1 in a million, probability of false match is above 50% with only 1609 samples

US Law and Biometrics

- Circuit splits on what 5th amendment covers.
- Broadly: some biometrics (e.g. face unlock) may *not* be protected
 - Some biometrics (e.g. fingerprint) *might* be protected
- Passcodes *are* protected

Attacking Biometrics

- An adversary might try to steal biometric info
 - Malicious fingerprint reader
 - Consider when biometric is used to derive a cryptographic key
 - Residual fingerprint on a glass

Passkeys (2024ish)

- An actual, deployed, genuine *password replacement*
 - *Also a 2fa replacement!*
 - *And a username replacement!*
- Basic goals:
 - Store some sort of key on user end-devices
 - Use that key to login to Stuff
 - Don't allow losing the key
 - Somehow make the key moving between devices Easy
