

CSE 490 GZ Introduction to Data Compression Winter 2002

Video Compression

Human Perception of Video

- 30 frames per second seems to allow the visual system to integrate the discrete frames into continuous perception.
- If distorted, nearby frames in the same scene should have **only** small details wrong.
 - A difference in average intensity is noticeable
- Compression choice when reducing bit rate
 - skipped frames cause stop action
 - lower fidelity frames may be better

CSE 490gz - Lecture 18 - Winter 2002

2

Applications of Digital Video

- Teleconference or video phone
 - Very low delay (1/10 second is a standard)
- Live Broadcast Video
 - Modest delay is tolerable (seconds is normal)
 - Error tolerance is needed.
- Video-in-a-can (DVD, Video-on-Demand)
 - Random access to compressed data is desired
 - Encoding can take a lot of time
- Decoding must always be at at least the frame rate.

CSE 490gz - Lecture 18 - Winter 2002

3

Video Encoding

Frame-by-Frame coding

Group-of-Frames coding

CSE 490gz - Lecture 18 - Winter 2002

4

Coding Techniques

- Frame-by-frame coding with prediction
 - Very low bit rates
 - low delay
 - Not error resilient
- Group-of-frames coding
 - Higher bit rates – within a group prediction is used
 - Error resilient
 - Random Access
 - Higher delay

CSE 490gz - Lecture 18 - Winter 2002

5

Digital Video Data

- CCIR 601 (4,2,2 scheme)
 - 13.5 MHz sample rate for luminance channel
 - 6.75 MHz sample rate for each of two chrominance channels
 - 8 bits per sample is a bit rate of $27 \times 8 = 216$ Mb per second
 - MPEG-SIF – $\frac{1}{2}$ sample rate for luminance and $\frac{1}{4}$ for chrominance – 81 Mb per second
- CIF (Common Interchange Format)
 - 288 x 352 pixels per frame for luminance channel
 - 144 x 176 pixels per frame for each of two chrominance
 - 8 bits per pixel and 30 frames per second gives 48.7 Mb per second
 - QCIF (Quarter - CIF) is $\frac{1}{4}$ the data or 12.2 Mb per second.

CSE 490gz - Lecture 18 - Winter 2002

6

High Compression Ratios Possible

- Nearby frames are highly correlated. Use the previous frame to predict the current one.
- Need to take advantage of the fact that usually objects move very little in $1/30$ th of a second.
 - Video coders use **motion compensation** as part of prediction

CSE 490gz - Lecture 18 - Winter 2002

7

Motion Compensation

Previous Frame

Frame

CSE 490gz - Lecture 18 - Winter 2002

8

Block Based Motion Compensation

motion compensation blocks

CSE 490gz - Lecture 18 - Winter 2002

9

Motion Vectors

motion vector = (0,0)

CSE 490gz - Lecture 18 - Winter 2002

10

Motion Vectors

motion vector = (20,5)
20 down and 5 to right

CSE 490gz - Lecture 18 - Winter 2002

11

Motion Vectors

motion vector = (0,-6)
0 down and 6 to left

CSE 490gz - Lecture 18 - Winter 2002

12

Motion Compensation

- For each motion compensation block
 - Find the block in the previous frame that gives the least distortion.
 - If the distortion is too high then code the block independently. (intra block)
 - Otherwise code the difference (inter block)

CSE 490gz - Lecture 18 - Winter 2002

13

Issues

- Distortion measured in squared error or absolute error
 - Absolute error is quicker to calculate
- Distortion measured from raw or compressed previous frame
 - Compressed is better because that is what the decoder has
- Block size
 - Too small then too many motion vectors
 - Too large then there may be no good match
- Searching range to find best block
 - Too large a search range is time consuming
 - Too small then may be better matches
 - Prediction can help.

CSE 490gz - Lecture 18 - Winter 2002

14

Rate Control

- After decoding, uncompressed stream is sent to a player.
 - We don't want to store the uncompressed stream
- Rate Control Problem
 - Frames are compressed at different rates
 - Solutions
 - Buffer the uncompressed frames for constant frame rate output.
 - Encode frames using a rate control algorithm to minimize the problem

CSE 490gz - Lecture 18 - Winter 2002

15

Rate Control

- The buffer is emptied at a constant rate 30 frames per second.
- The buffer is filled at a variable rate. But its average rate is 30 frames per second.

CSE 490gz - Lecture 18 - Winter 2002

16

Rate Control Situations

- Encoded data can be requested quickly (DVD or other storage medium)
 - Frames can always be decoded in time less than the 30 frames per second.
 - Decoder requests encoded frames to keep the buffer from overflowing.
- Encoded data received without request (Streaming media on the internet)
 - Encoder should anticipate what the decoder and buffer will be doing and encode using a rate control algorithm.

CSE 490gz - Lecture 18 - Winter 2002

17

Simple Rate Control Algorithm

- If the buffer would overflow then compress the frames less.
- If the buffer would underflow then compress frames more.
 - Extreme case – skip frames to catch up. The decoder on not receiving a frame will send of copy of the current frame to the player. This is what causes the stop action or gaps in video.
 - If frame arrive too late to be played the decoder will throw it away.

CSE 490gz - Lecture 18 - Winter 2002

18

H.261

- Application – low bit rate streaming video
- Frame-by-frame encoder
- DCT based with 8x8 coding block
 - Uses JPEG style coding
- Motion compensation based on 16x16 macroblocks.

CSE 490gz - Lecture 18 - Winter 2002

19

H.261

CSE 490gz - Lecture 18 - Winter 2002

20

H.261(QCIF)

CSE 490gz - Lecture 18 - Winter 2002

21

H.261

- Within a group of blocks (GOB) prediction is used with motion vectors for coding.

CSE 490gz - Lecture 18 - Winter 2002

22

H.261 Organization

CSE 490gz - Lecture 18 - Winter 2002

23

P-Frame

CSE 490gz - Lecture 18 - Winter 2002

24

Intra-Macroblock Distribution

25

MPEG-1

- Application – Video coding for random access
- Group-of-frames encoder
- DCT based with 8x8 coding block
 - Uses JPEG style coding
- Motion compensation based on 16x16 macroblocks.
- Forward and Backward Prediction within a group of frames

CSE 490gz - Lecture 18 - Winter 2002

26

MPEG-1

27

Orders

Display Order

Coding/Decoding Order

Added delay is one frame time

CSE 490gz - Lecture 18 - Winter 2002

28

MPEG-1 Notes

- Random access unit = Group-of-Frame
 - Called GOP for group-of-pictures
- Error resilient
 - B-frames can be damaged without propagation
- Added delay
 - Coding order different than display order
- Encoding time consuming
 - Suitable for non-interactive applications

CSE 490gz - Lecture 18 - Winter 2002

29

Beyond MPEG-1

- MPEG-2
 - Application independent standard
- MPEG-4
 - Multimedia applications
 - Model based coding
- H.263
 - More error resilience
- 3-D Wavelet Coding
 - Third dimension is time
 - 3-D SPIHT has been implemented and claims have been made
 - Delay is large because GOP is large

CSE 490gz - Lecture 18 - Winter 2002

30

Questions

- Can bit-plane coding replace JPEG style coding to improve video compression?
- Motion compensation is very time consuming and is not done for some real-time high bandwidth applications. Is there a good alternative to block based motion compensation?
