CSE505: Graduate Programming Languages Lecture 4 — Proofs About Operational Semantics Dan Grossman Fall 2012	<section-header><section-header><section-header><list-item><list-item><list-item><list-item><list-item><list-item></list-item></list-item></list-item></list-item></list-item></list-item></section-header></section-header></section-header>
First proof	Second proof
 Key points from the proof of the barely-interesting fact that while 1 skip diverges: First carefully state theorem in terms that can be proven by induction In this case on n, the number of steps taken Must get induction hypothesis "just right" Not too weak: proof doesn't go through Not too strong: can't prove something false Stronger induction hypothesis means implies the original claim Often obvious 	 Key points from the proof of the "no negatives" property: Showing a property is <i>preserved</i> is about <i>invariants</i>, a fundamental software-development concept Can define a program property via judgments and prove it holds after every step "Inverting assumed derivations" gives you necessary facts for smaller expressions/statements (e.g., the while case) <i>Inversion</i> is the technique of saying, "By <i>assumption</i>, there is a derivation of X. In <i>this case</i> of the proof, such a derivation <i>must</i> end with rule Y (no other rule matches). Therefore the hypotheses of that rule must hold here." A common pattern: induction, cases, inversion in each case
Dan Grossman CSE505 Fall 2012, Lecture 4 3	Dan Grossman CSE505 Fall 2012, Lecture 4 4
Motivation of non-negatives While "no negatives preserved" boils to down to properties of blue-+ and blue-*, writing out the whole proof ensures our language has no mistakes or bad interactions • Like a system test for the semantics The theorem is false if we have: • Overly flexible rules, e.g.: $\overline{H}; c \Downarrow c'$ • An "unsafe" language like C: $\frac{H(x) = \{c_0, \dots, c_{n-1}\} H; e \Downarrow c \qquad c \ge n}{H; x[e] := e' \to H'; s'}$	 Even more general proofs to come We defined the semantics Given our semantics, we established properties of programs and sets of programs More interesting is having multiple semantics—for what program states are they equivalent? (For what notion of equivalence?) Or having a more abstract semantics (e.g., a type system) and asking if it is preserved under evaluation. (If e has type τ and e becomes e', does e' have type τ?) But first a one-lecture detour to "denotational" semantics
