Classless OOP

OOP gave us code-reuse via inheritance and extensibility via late-binding

Can we throw out classes and still get OOP? Yes

Can it have a type system that prevents “no match found” and “no best match” errors? Yes, but we won’t get there

This is mind-opening stuff if you’ve never seen it

*Will make up syntax as we go...*
Make objects directly

Everything is an object. You can make objects directly:

let p = [
    field x = 7;
    field y = 9;
    right_quad(){ x.gt(0) && y.gt(0) } // cf. 0.lte(y)
]

p now bound to an object

- Can invoke its methods and read/write its fields

No classes: Constructors are easy to encode

let make_pt = [
    doit(x0,y0) { [ field x=x0; field y=y0;... ] } ]
Inheritance and Override

Building objects from scratch won’t get us late-binding and code reuse. Here’s the trick:

- clone method produces a (shallow) copy of an object
- method “slots” can be mutable

```javascript
let o1 = [ // still have late-binding
  odd(x) {if x.eq(0) then false else self.even(x-1)}
  even(x) {if x.eq(0) then true else self.odd(x-1)}
]
let o2 = o1.clone()
o2.even(x) := {(x.mod(2)).eq(0)}
```

Language doesn’t grow: just methods and mutable “slots”
Can use for constructors too: clone and assign fields
Extension

But that trick doesn’t work to add slots to an object, a common use of subclassing

Having something like “extend e1 (x=e2)” that mutates e1 to have a new slot is problematic semantically (what if e1 has a slot named x) and for efficiency (may not be room where e1 is allocated)

Instead, we can build a new object with a special parent slot: [parent=e1; x=e2]

parent is very special because definition of method-lookup (the issue in OO) depends on it (else this isn’t inheritance)
Method Lookup

To find the \( m \) method of \( o \):

- Look for a slot named \( m \)
- If not found, look in object held in parent slot

But we still have late-binding: for method in parent slot, we still have \texttt{self} refer to the original \( o \).

Two \textit{inequivalent} ways to define \texttt{parent=e1}:

- Delegation: parent refers to result of \texttt{e1}
- Embedding: parent refers to result of \texttt{e1.clone()}

Mutation of result of \texttt{e1} (or its parent or grandparent or ...) exposes the difference

- We’ll assume delegation
Oh so flexible

Delegation is way more flexible (and simple!) (and dangerous!) than class-based OO: The object being delegated to is usually used like a class, but its slots may be mutable

- Assigning to a slot in a delegated object changes every object that delegates to it (transitively)
  - Clever change-propagation but as dangerous as globals and arguably more subtle?

- Assigning to a parent slot is “dynamic inheritance” — changes where slots are inherited from

Classes restrict what you can do and how you think, e.g., never thinking of clever run-time modifications of inheritance
Javascript: A Few Notes

- Javascript gives assignment “extension” semantics if field not already there. Implementations use indirection (hashtables).
- *parent* is called *prototype*
- `new F(...)` creates a new object `o`, calls `F` with `this` bound to `o`, and returns `o`
  - No special notion of constructor
  - Functions are objects too
  - This isn’t quite prototype-based inheritance, but can code it up:

```javascript
function inheritFrom(o) {
    function F() {
    
    F.prototype = o;
    return new F();
    }
}
```
- No clone (depending on version), but can copy fields explicitly
Rarely what you want

We have the essence of OOP in a tiny language with more flexibility than we usually want

Avoid it via careful coding idioms:
- Create *trait/abstract* objects: Just immutable methods
  - Analogous role to virtual-method tables
- Extend with *prototype/template* objects: Add mutable fields but don’t mutate them
  - Analogous role to classes
- Clone prototypes to create *concrete/normal* objects
  - Analogous role to objects (clone is constructor)

Traits can extend other traits and prototypes other prototypes
- Analogous to subclassing
Coming full circle

This idiom is so important, it’s worth having a type system that enforces it.

For example, a template object cannot have its members accessed (except clone).

We end up getting close to classes, but from first principles and still allowing the full flexibility when you want it.
