# Important Techniques in Neural Network Training

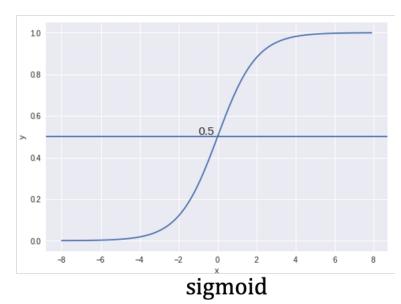

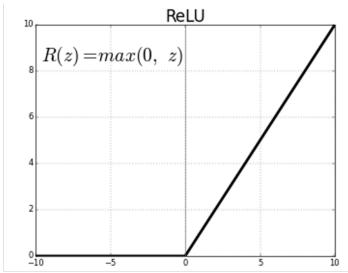

#### **Gradient Explosion / Vanishing**

- Deeper networks are harder to train:
  - Intuition: gradients are products over layers
  - Hard to control the learning rate

#### **Activation Functions**

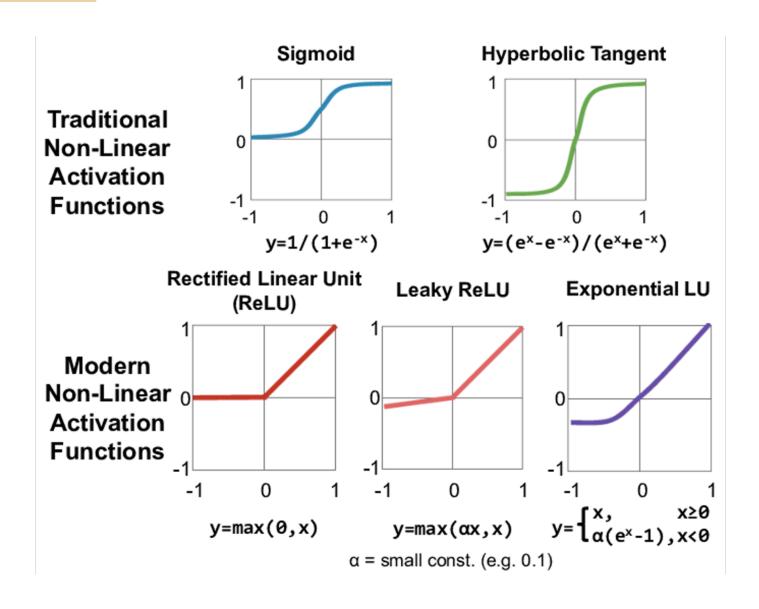

**Rectified Linear United** 

#### **Activation Function**

#### Initialization

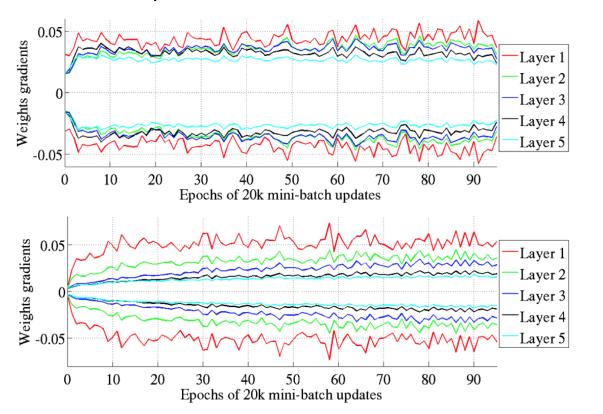

- Zero-initialization
- Large initialization
- Small initialization

- Design principles:
  - Zero activation mean
  - Activation variance remains same across layers

# Xavier Initialization (Glorot & Bengio, '10)

$$W_{ij}^{(h)} \sim \text{Unif} \left[ -\frac{\sqrt{6}}{\sqrt{d_h + d_{h+1}}}, \frac{\sqrt{6}}{\sqrt{d_h + d_{h+1}}} \right]$$
 
$$b^{(h)} = 0$$

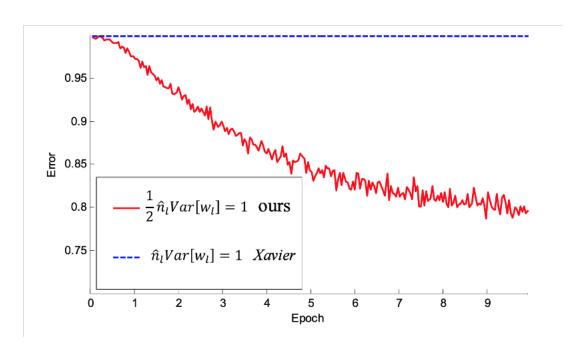

- Experiments (tanh activation)

# Kaiming Initialization (He et al. '15)

• 
$$W_{ij}^{(h)} \sim \mathcal{N}\left(0, \frac{2}{d_h}\right)$$
.

- $b^{(h)} = 0$
- Designed for ReLU activation
- 30-layer neural network

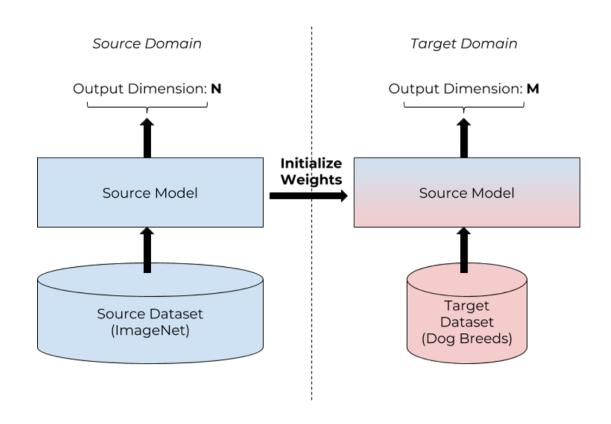

# Kaiming Initialization (He et al. '15)

# Kaiming Initialization (He et al. '15)

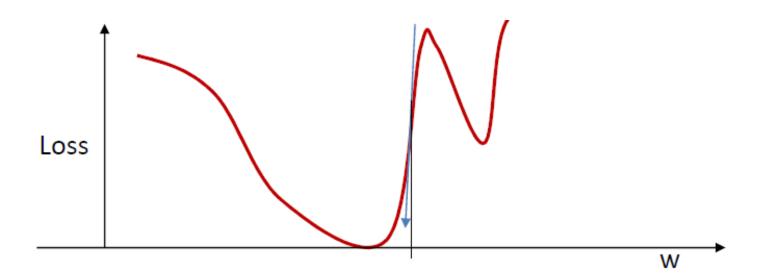

#### **Initialization by Pre-training**

- Use a pre-trained network as initialization
- And then fine-tuning

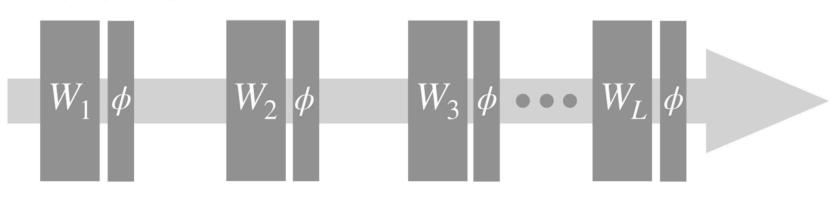

#### **Gradient Clipping**

- The loss can occasionally lead to a steep descent
- This result in immediate instability
- If gradient norm bigger than a threshold, set the gradient to the threshold.

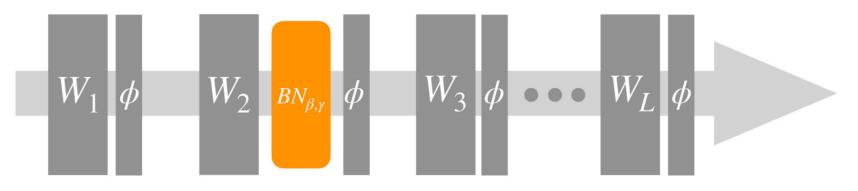

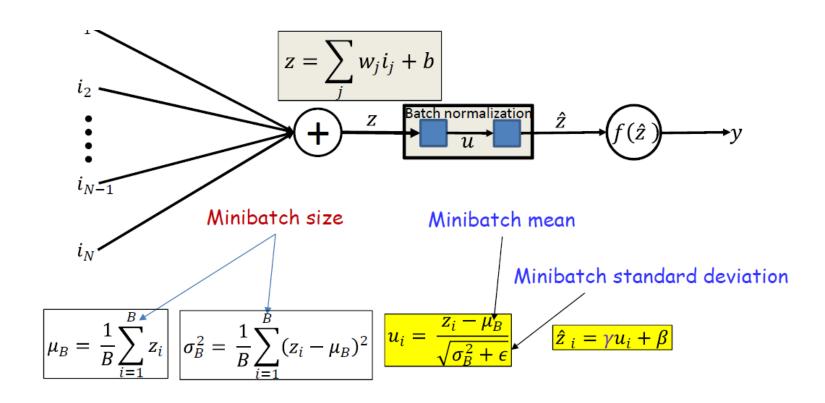

- Normalizing/whitening (mean = 0, variance = 1) the inputs is generally useful in machine learning.
  - Could normalization be useful at the level of hidden layers?
  - Internal covariate shift: the calculations of the neural networks change the distribution in hidden layers even if the inputs are normalized
- Batch normalization is an attempt to do that:
  - Each unit's pre-activation is normalized (mean subtraction, std division)
  - During training, mean and std is computed for each minibatch (can be backproped!

Adding a BatchNorm layer (between weights and activation function)

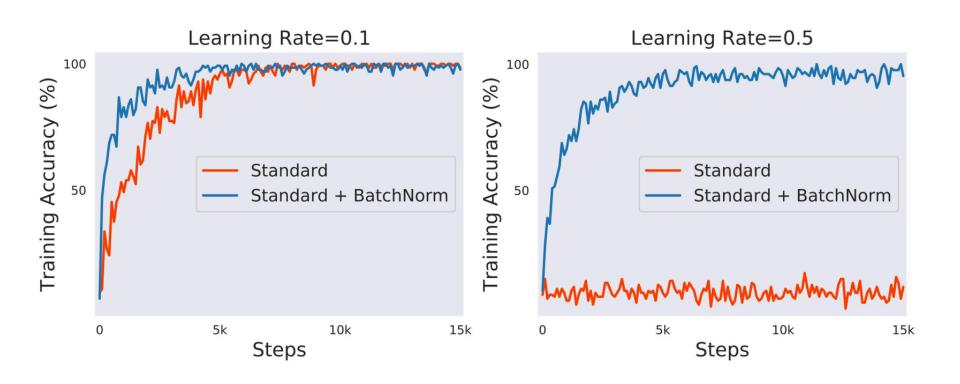

- BatchNorm at training time
  - Standard backprop performed for each single training data
  - Now backprop is performed over entire batch.

$$\frac{\partial Div}{\partial \sigma_B^2} = \frac{-1}{2} (\sigma_B^2 + \epsilon)^{-3/2} \sum_{i=1}^B \frac{\partial Div}{\partial u_i}$$

$$\frac{\partial Div}{\partial \mu_B} = \frac{-1}{\sqrt{\sigma_B^2 + \epsilon}} \sum_{i=1}^B \frac{\partial Div}{\partial u_i}$$

$$i_1 \frac{\partial Div}{\partial z_i} = \frac{\partial Div}{\partial u_i} \cdot \frac{1}{\sqrt{\sigma_B^2 + \epsilon}} + \frac{\partial Div}{\partial \sigma_B^2} \cdot \frac{2(z_i - \mu_B)}{B} + \frac{\partial Div}{\partial \mu_B} \cdot \frac{1}{B}$$

$$i_2 \frac{\partial Div}{\partial z_i} = \frac{\partial Div}{\partial u_i} \cdot \frac{1}{\sqrt{\sigma_B^2 + \epsilon}} + \frac{\partial Div}{\partial \sigma_B^2} \cdot \frac{2(z_i - \mu_B)}{B} + \frac{\partial Div}{\partial \mu_B} \cdot \frac{1}{B}$$
The rest of backprop continues from  $\frac{\partial Div}{\partial z_i}$ 

#### What is BatchNorm actually doing?

- May not due to covariate shift (Santurkar et al. '18):
  - Inject non-zero mean, non-standard covariance Gaussian noise after BN layer: removes the whitening effect
  - Still performs well.
- Only training  $\beta$ ,  $\gamma$  with random convolution kernels gives nontrivial performance (Frankle et al. '20)
- BN can use exponentially increasing learning rate! (Li & Arora '19)

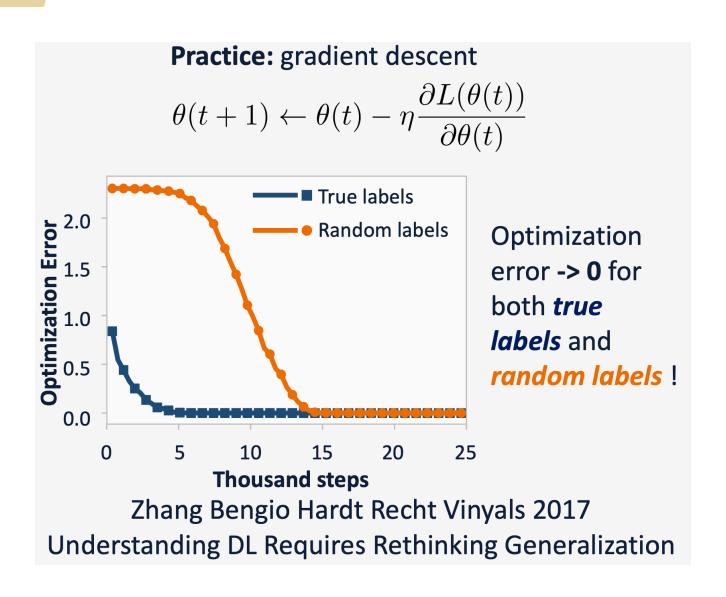

#### More normalizations

- Layer normalization (Ba, Kiros, Hinton, '16)
  - Batch-independent
  - Suitable for RNN, MLP
- Weight normalization (Salimans, Kingma, '16)
  - Suitable for meta-learning (higher order gradients are needed)
- Instant normalization (Ulyanov, Vedaldi, Lempitsky, '16)
  - Batch-independent, suitable for generation tasks
- Group normalization (Wu & He, '18)
  - Batch-independent, improve BatchNorm for small batch size

# Non-convex<br/>Optimization Landscape

#### Gradient descent finds global minima

# Types of stationary points

- Stationary points:  $x : \nabla f(x) = 0$
- Global minimum:

$$x: f(x) \le f(x') \, \forall x' \in \mathbb{R}^d$$

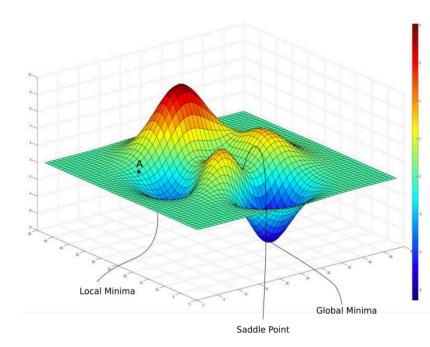

• Local minimum:

$$x: f(x) \le f(x') \, \forall x': \|x - x'\| \le \epsilon$$

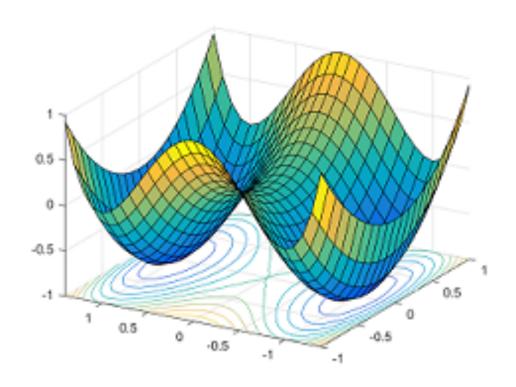

· Local maximum:

$$x: f(x) \ge f(x') \forall x': ||x - x'|| \le \epsilon$$

 Saddle points: stationary points that are not a local min/max

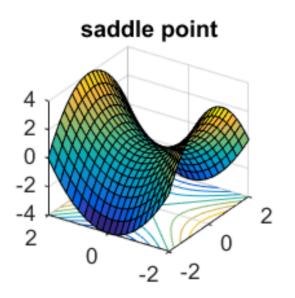

#### **Landscape Analysis**

- All local minima are global!
- Gradient descent can escape saddle points.

#### Strict Saddle Points (Ge et al. '15, Sun et al. '15)

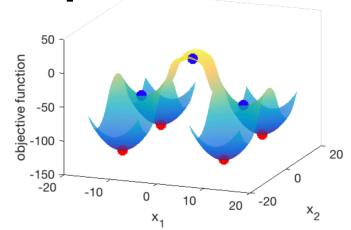

• Strict saddle point: a saddle point and  $\lambda_{\min}(\nabla^2 f(x)) < 0$ 

#### **Escaping Strict Saddle Points**

- Noise-injected gradient descent can escape strict saddle points in polynomial time [Ge et al., '15, Jin et al., '17].
- Randomly initialized gradient descent can escape all strict saddle points asymptotically [Lee et al., '15].
  - Stable manifold theorem.

 Randomly initialized gradient descent can take exponential time to escape strict saddle points [Du et al., '17].

If 1) all local minima are global, and 2) are saddle points are strict, then noise-injected (stochastic) gradient descent finds a global minimum in polynomial time

#### What problems satisfy these two conditions

- Matrix factorization
- Matrix sensing
- Matrix completion
- Tensor factorization
- Two-layer neural network with quadratic activation

#### What about neural networks?

• Linear networks (neural networks with linear activations functions): all local minima are global, but there exists saddle points that are not strict [Kawaguchi '16].

- Non-linear neural networks with:
  - Virtually any non-linearity,
  - Even with Gaussian inputs,
  - Labels are generated by a neural network of the same architecture,

There are many bad local minima [Safran-Shamir '18, Yun-Sra-Jadbaie '19].
