3 Announcements

We are releasing HW1 today
- It is due in 2 weeks (1/19 at 23:59pm)
- The homework is long
  - Requires proving theorems as well as coding
- Please start early

Releasing Colab 0 and Colab 1 today

Recitation sessions:
- Spark Tutorial using Colab 0:
  Today, Jan 5, 3:30-5pm CSE2 371
Frequent Itemset Mining & Association Rules

CS547 Machine Learning for Big Data
Tim Althoff

PAUL G. ALLEN SCHOOL OF COMPUTER SCIENCE & ENGINEERING
Association Rule Discovery

Supermarket shelf management – Market-basket model:

- **Goal:** Identify items that are bought together by sufficiently many customers
- **Approach:** Process the sales data collected with barcode scanners to find dependencies among items
- **A “classic” rule:**
  - If someone buys diaper and milk, then he/she is likely to buy beer
  - Don’t be surprised if you find six-packs next to diapers!
The Market-Basket Model

- **A large set of items**
  - e.g., things sold in a supermarket

- **A large set of baskets**
  - Each basket is a small subset of items
    - e.g., the things one customer buys on one day (or “cart”)

- Discover association rules:
  - People who bought \{x,y,z\} tend to buy \{v,w\}
    - Example applications: Amazon, Spotify, Walmart...

---

**Input:**

<table>
<thead>
<tr>
<th>Basket</th>
<th>Items</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Bread, Coke, Milk</td>
</tr>
<tr>
<td>2</td>
<td>Beer, Bread</td>
</tr>
<tr>
<td>3</td>
<td>Beer, Coke, Diaper, Milk</td>
</tr>
<tr>
<td>4</td>
<td>Beer, Bread, Diaper, Milk</td>
</tr>
<tr>
<td>5</td>
<td>Coke, Diaper, Milk</td>
</tr>
</tbody>
</table>

**Output:**

**Rules Discovered:**

\{Milk\} --> \{Coke\}
\{Diaper, Milk\} --> \{Beer\}
More generally

- A general many-to-many mapping (association) between two kinds of things
  - But we ask about connections among "items", not "baskets"

- Items and baskets are abstract:
  - For example:
    - Items/baskets can be products/shopping basket
    - Items/baskets can be words/documents
    - Items/baskets can be basepairs/genes
    - Items/baskets can be drugs/patients
Applications – (1)

- **Items** = products; **Baskets** = sets of products someone bought in one trip to the store
- **Real market baskets:** Chain stores keep TBs of data about what customers buy together
  - Tells how typical customers navigate stores, lets them position tempting items:
    - Apocryphal story of “diapers and beer” discovery
    - Used to position potato chips between diapers and beer to enhance sales of potato chips
- **Amazon’s ‘people who bought X also bought Y’**
Applications – (2)

- **Baskets** = sentences; **Items** = documents in which those sentences appear
  - Items that appear together too often could represent plagiarism
  - Notice items do not have to be “in” baskets

- **Baskets** = patients; **Items** = drugs & side-effects
  - Has been used to detect combinations of drugs that result in particular side-effects
  - **But requires extension**: Absence of an item needs to be observed as well as presence
First: Define

Frequent itemsets

Association rules:

Confidence, Support, Interestingness

Then: Algorithms for finding frequent itemsets

Finding frequent pairs

A-Priori algorithm

PCY algorithm
Frequent Itemsets

- **Simplest question:** Find sets of items that appear together “frequently” in baskets
  - **Support** for itemset $I$: Number of baskets containing all items in $I$
    - (Often expressed as a fraction of the total number of baskets)

- Given a **support threshold $s$**, then sets of items that appear in at least $s$ baskets are called **frequent itemsets**

<table>
<thead>
<tr>
<th>TID</th>
<th>Items</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Bread, Coke, Milk</td>
</tr>
<tr>
<td>2</td>
<td>Beer, Bread</td>
</tr>
<tr>
<td>3</td>
<td>Beer, Coke, Diaper, Milk</td>
</tr>
<tr>
<td>4</td>
<td>Beer, Bread, Diaper, Milk</td>
</tr>
<tr>
<td>5</td>
<td>Coke, Diaper, Milk</td>
</tr>
</tbody>
</table>

Support of \{Beer, Bread\} = 2
Example: Frequent Itemsets

- **Items** = \{milk, coke, pepsi, beer, juice\}
- **Support threshold** = 3 baskets
  
  \[B_1 = \{m, c, b\} \quad B_2 = \{m, p, j\}\]
  
  \[B_3 = \{m, b\} \quad B_4 = \{c, j\}\]
  
  \[B_5 = \{m, p, b\} \quad B_6 = \{m, c, b, j\}\]
  
  \[B_7 = \{c, b, j\} \quad B_8 = \{b, c\}\]

- **Frequent itemsets**: \{m\}, \{c\}, \{b\}, \{j\}, \{m, b\}, \{b, c\}, \{c, j\}.
Define: Association Rules

- Define: Association Rules:
  If-then rules about the contents of baskets
- \{i_1, i_2, \ldots, i_k\} \rightarrow j \text{ means: “if a basket contains all of } i_1, \ldots, i_k \text{ then it is likely to contain } j”
- In practice there are many rules, want to find significant/interesting ones!
- **Confidence** of association rule is the probability of } j \text{ given } I = \{i_1, \ldots, i_k\}

\[
\text{conf}(I \rightarrow j) = \frac{\text{support}(I \cup j)}{\text{support}(I)}
\]
Where confidence falls short

What if everyone buys milk?

\[
\begin{align*}
\text{conf}\left(\{\text{Beer}\} \rightarrow \text{Milk}\right) &= 1 \\
\text{conf}\left(\{\text{Bread}\} \rightarrow \text{Milk}\right) &= 1 \\
\ldots \\
\text{conf}\left(\{\text{Beer, Bread, Diapers}\} \rightarrow \text{Milk}\right) &= 1
\end{align*}
\]

We have 100% confidence for \( I \rightarrow \text{milk} \), no matter what \( I \) we choose!
Interesting Association Rules

- Not all high-confidence rules are interesting
  - The rule $X \rightarrow \text{milk}$ may have high confidence for many itemsets $X$, because milk is just purchased very often (independent of $X$) and the confidence will be high

- **Interest** of an association rule $I \rightarrow j$:
  - abs. difference between its confidence and the fraction of baskets that contain $j$
  - $\text{Interest}(I \rightarrow j) = |\text{conf}(I \rightarrow j) - \Pr[j]|$

  - Interesting rules are those with high positive or negative interest values (usually above 0.5)
Example: Confidence and Interest

\[
\begin{align*}
B_1 &= \{m, c, b\} & B_2 &= \{m, p, j\} \\
B_3 &= \{m, b\} & B_4 &= \{c, j\} \\
B_5 &= \{m, p, b\} & B_6 &= \{m, c, b, j\} \\
B_7 &= \{c, b, j\} & B_8 &= \{b, c\}
\end{align*}
\]

- **Association rule**: \( \{m, b\} \rightarrow c \)
  - **Support** = 2
  - **Confidence** = \( \frac{2}{4} = 0.5 \)
  - **Interest** = \( |0.5 - \frac{5}{8}| = \frac{1}{8} \)
    - Item \( c \) appears in \( \frac{5}{8} \) of the baskets
    - The rule is not very interesting!
Focus on Mining Association Rules

- **Problem:** Find all association rules with support $\geq s$ and confidence $\geq c$

- **Note:** Support of an association rule is the support of the set of items in the rule (left and right side)

- **Hard part:** Finding the frequent itemsets!

- If $\{i_1, i_2, \ldots, i_k\} \rightarrow j$ has high support and confidence, then both $\{i_1, i_2, \ldots, i_k\}$ and $\{i_1, i_2, \ldots, i_k, j\}$ will be “frequent”

\[
conf(I \rightarrow j) = \frac{support(I \cup j)}{support(I)}
\]
Mining Association Rules

- **Step 1:** Find all frequent itemsets $I$ (we will explain this next)
- **Step 2:** Rule generation
  - For every subset $A$ of $I$, generate a rule $A \rightarrow I \setminus A$
    - Since $I$ is frequent, $A$ is also frequent (monotonicity)
    - **Variant 1:** Single pass to compute the rule confidence
      - $\text{confidence}(A, B \rightarrow C, D) = \frac{\text{support}(A, B, C, D)}{\text{support}(A, B)}$
    - **Variant 2:**
      - **Observation:** If $A, B, C \rightarrow D$ is below confidence, so is $A, B \rightarrow C, D$
      - Can generate “bigger” rules from smaller ones!
  - **Output the rules above the confidence threshold**
Example

\[ B_1 = \{m, c, b\} \quad B_2 = \{m, p, j\} \]
\[ B_3 = \{m, c, b, n\} \quad B_4 = \{c, j\} \]
\[ B_5 = \{m, p, b\} \quad B_6 = \{m, c, b, j\} \]
\[ B_7 = \{c, b, j\} \quad B_8 = \{b, c\} \]

- **Support threshold** \( s = 3 \), **confidence** \( c = 0.75 \)

- **Step 1)** Find frequent itemsets:
  - \( \{b, m\} \quad \{b, c\} \quad \{c, m\} \quad \{c, j\} \quad \{m, c, b\} \)

- **Step 2)** Generate rules:
  - \( b \rightarrow m: c = 4/6 \)  \( b \rightarrow c: c = 5/6 \)  \( b, c \rightarrow m: c = 3/5 \)
  - \( m \rightarrow b: c = 4/5 \)  \( \ldots \)  \( b, m \rightarrow c: c = 3/4 \)
  - \( b \rightarrow c, m: c = 3/6 \)
Compacting the Output

- To reduce the number of rules, we can post-process them and only output:
  - **Maximal frequent itemsets:**
    No immediate superset (same set and one additional item) is frequent
    - Gives more pruning
  - **Closed itemsets:**
    No immediate superset has the same support (> 0)
    - Stores not only frequent information, but exact supports/counts
### Example: Maximal/Closed

<table>
<thead>
<tr>
<th></th>
<th>Support</th>
<th>Frequent ((s=3))</th>
<th>Maximal</th>
<th>Closed</th>
</tr>
</thead>
<tbody>
<tr>
<td>A</td>
<td>4</td>
<td>Yes</td>
<td>No</td>
<td>No</td>
</tr>
<tr>
<td>B</td>
<td>5</td>
<td>Yes</td>
<td>No</td>
<td>Yes</td>
</tr>
<tr>
<td>C</td>
<td>3</td>
<td>Yes</td>
<td>No</td>
<td>No</td>
</tr>
<tr>
<td>AB</td>
<td>4</td>
<td>Yes</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>AC</td>
<td>2</td>
<td>No</td>
<td>No</td>
<td>No</td>
</tr>
<tr>
<td>BC</td>
<td>3</td>
<td>Yes</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>ABC</td>
<td>2</td>
<td>No</td>
<td>No</td>
<td>Yes</td>
</tr>
</tbody>
</table>

- Superset AB also frequent
- Superset BC has same support
- ABC (only superset) not freq
- ABC (only superset) has smaller support
Step 1: Finding Frequent Itemsets
Itemsets: Computation Model

- **Back to finding frequent itemsets**
- Typically, data is kept in flat files rather than in a database system:
  - Stored on disk
  - Stored basket-by-basket
  - Baskets are **small** but we have many baskets and many items
    - Expand baskets into pairs, triples, etc. as you read baskets
    - Use $k$ nested loops to generate all sets of size $k$

**Note:** We want to find frequent itemsets. To find them, we have to count them. To count them, we have to enumerate them.
The true cost of mining disk-resident data is usually the **number of disk I/Os**.

In practice, association-rule algorithms read the data in **passes** – all baskets read in turn.

We measure the cost by the **number of passes** an algorithm makes over the data.
Main-Memory Bottleneck

- For many frequent-itemset algorithms, **main-memory** is the critical resource
  - As we read baskets, we need to count something, e.g., occurrences of pairs of items
  - The number of different things we can count is limited by main memory
  - Swapping counts in/out is a disaster
    - Swapping means having to push memory to/from disk because memory was too small.
Finding Frequent Pairs

- The hardest problem often turns out to be finding the frequent **pairs** of items \( \{i_1, i_2\} \)
  - **Why?** Freq. pairs are common, freq. triples are rare
    - **Why?** Probability of being frequent drops exponentially with size; number of sets grows more slowly with size
- Let’s first concentrate on pairs, then extend to larger sets
- The approach:
  - We always need to generate all the itemsets
  - But we would only like to count (keep track) of those itemsets that in the end turn out to be frequent
Naïve Algorithm

- **Naïve approach to finding frequent pairs**
- Read file once, counting in main memory the occurrences of each pair:
  - From each basket of $n$ items, generate its $\frac{n(n-1)}{2}$ pairs by two nested loops
- **Fails if (#items)$^2$ exceeds main memory**
  - **Remember:** #items can be 100K (Wal-Mart) or 10B (Web pages)
    - Suppose $10^5$ items, counts are 4-byte integers
    - Number of pairs of items: $10^5(10^5-1)/2 \approx 5*10^9$
    - Therefore, $2*10^{10}$ (20 gigabytes) of memory is needed
Counting Pairs in Memory

Goal: Count the number of occurrences of each pair of items \((i,j)\):

- **Approach 1**: Count all pairs using a matrix

- **Approach 2**: Keep a table of triples \([i, j, c] = \) “the count of the pair of items \{i, j\} is c.”
  - If integers and item ids are 4 bytes, we need approximately 12 bytes for pairs with count \(> 0\)
  - Plus some additional overhead for the hashtable
Comparing the 2 Approaches

Triangular Matrix

Item i

Item j

4 bytes per pair

Triples

12 per occurring pair
Comparing the two approaches

- **Approach 1: Triangular Matrix**
  - \( n \) = total number items
  - Count pair of items \( \{i, j\} \) only if \( i < j \)
  - Keep pair counts in lexicographic order:
    - \( \{1,2\}, \{1,3\}, ..., \{1,n\}, \{2,3\}, \{2,4\}, ..., \{2,n\}, \{3,4\}, ... \)
  - Pair \( \{i, j\} \) is at position: \([n(n - 1) - (n - i)(n - i + 1)]/2 + (j - i)\)
  - Total number of pairs \( n(n - 1)/2 \); total bytes = \( O(n^2) \)
  - **Triangular Matrix** requires 4 bytes per pair

- **Approach 2** uses **12 bytes** per occurring pair (but only for pairs with count > 0)

- Approach 2 beats Approach 1 if less than \( 1/3 \) of possible pairs actually occur
Comparing the two approaches

- **Approach 1: Triangular Matrix**
  - \( n = \) total number items
  - Count pair of items \( \{i, j\} \) only if \( i < j \)
  - Keep pair counts in lexicographic order:
    - \( \{1, 2\}, \{1, 3\}, \ldots, \{1, n\}, \{2, 3\}, \{2, 4\}, \ldots, \{2, n\}, \{3, 4\}, \ldots \)
  - Pair \( \{i, j\} \) is at position:
    \[
    \frac{n(n-1)}{2} - (n-i)(n-i+1) + (j-i)
    \]
  - Total number of pairs \( n(n-1)/2 \); total bytes = \( O(n^2) \)
  - Triangular Matrix requires 4 bytes per pair

- **Approach 2** uses 12 bytes per occurring pair (but only for pairs with count > 0)

-- Approach 2 beats Approach 1 if less than \( 1/3 \) of possible pairs actually occur

Problem is if we have too many items so the pairs do not fit into memory.

Can we do better?
A-Priori Algorithm

- Monotonicity of “Frequent”
- Notion of Candidate Pairs
- Extension to Larger Itemsets
A two-pass approach called A-Priori limits the need for main memory

Key idea: monotonicity

- If a set of items $I$ appears at least $s$ times, so does every subset $J$ of $I$

Contrapositive for pairs:
If item $i$ does not appear in $s$ baskets, then no pair including $i$ can appear in $s$ baskets

So, how does A-Priori find freq. pairs?
A-Priori Algorithm – (2)

- **Pass 1:** Read baskets and count in main memory the # of occurrences of each *individual item*
  - Requires only memory proportional to #items

- **Items that appear ≥ s times are the frequent items**

- **Pass 2:** Read baskets again and keep track of the count of only those pairs where both elements are frequent (from Pass 1)
  - Requires memory proportional to square of frequent items only (for counts)
  - Plus a list of the frequent items (so you know what must be counted)
Main-Memory: Picture of A-Priori

Green box represents the amount of available main memory. Smaller boxes represent how the memory is used.
You can use the triangular matrix method with \( n \) = number of frequent items
- May save space compared with storing triples

**Trick:** re-number frequent items 1, 2, ... and keep a table relating new numbers to original item numbers
Frequent Triples, Etc.

- For each $k$, we construct two sets of $k$-tuples (sets of size $k$):
  - $C_k =$ candidate $k$-tuples = those that might be frequent sets (support $\geq s$) based on information from the pass for $k-1$
  - $L_k =$ the set of truly frequent $k$-tuples

```
All items
\rightarrow C_1 \rightarrow \text{Filter} \rightarrow L_1 \rightarrow \text{Construct} \rightarrow C_2 \rightarrow \text{Filter} \rightarrow L_2 \rightarrow \text{Construct} \rightarrow C_3
```

All pairs of items from $L_1$

Count the items

Count the pairs

To be explained
Example

\( \text{baskets} \)
- \{m, c, b\}
- \{m, p, j\}
- \{m, c, b, n\}
  - \{c, j\}
  - \{m, p, b\}
- \{m, c, b, j\}
  - \{c, b, j\}
  - \{b, c\}

\( s = 3 \)

\( C_1 = \{ \{b\}, \{c\}, \{j\}, \{m\}, \{n\}, \{p\} \} \)
- Supports: \{b\} \rightarrow 6, \{c\} \rightarrow 6, \{j\} \rightarrow 4,
  \{m\} \rightarrow 5, \{n\} \rightarrow 1, \{p\} \rightarrow 2

\( L_1 = \{ \{b\}, \{c\}, \{j\}, \{m\} \} \)

\( C_2 = \{ \{b, c\}, \{b, j\}, \{b, m\}, \{c, j\}, \{c, m\}, \{j, m\} \} \)
- Supports: \{b, c\} \rightarrow 5, \{b, j\} \rightarrow 2, \{b, m\} \rightarrow 4
  \{c, j\} \rightarrow 3, \{c, m\} \rightarrow 3, \{j, m\} \rightarrow 2

\( L_2 = \{ \{b, c\}, \{b, m\}, \{c, j\}, \{c, m\} \} \)

\( C_3 = \{ \{b, c, m\}, \{b, c, j\}, \{b, m, j\}, \{c, m, j\} \} \)
- Supports: \{b, c, m\} \rightarrow 3

\( L_3 = \{ \{b, c, m\} \} \)

** In order for a triple to be frequent, the three pairs it contains must all be frequent.**
A-Priori for All Frequent Itemsets

- One pass for each $k$ (itemset size)
- Needs room in main memory to count each candidate $k$–tuple
- For typical market-basket data and reasonable support (e.g., 1%), $k = 2$ requires the most memory

- Many possible extensions:
  - Association rules with intervals:
    - For example: Men over 65 have 2 cars
  - Association rules when items are in a taxonomy
    - Bread, Butter $\rightarrow$ FruitJam
    - BakedGoods, MilkProduct $\rightarrow$ PreservedGoods
  - Lower the support $s$ as itemset gets bigger
PCY (Park-Chen-Yu) Algorithm

- Improvement to A-Priori
- Exploits Empty Memory on First Pass
- Frequent Buckets
Observation:
In pass 1 of A-Priori, most memory is idle
- We store only individual item counts
- Can we use the idle memory to reduce memory required in pass 2?

Pass 1 of PCY: In addition to item counts, maintain a hash table with as many buckets as fit in memory
- Keep a count for each bucket into which pairs of items are hashed
  - For each bucket just keep the count, not the actual pairs that hash to the bucket!

Note: Bucket≠Basket
Hash Functions

- A **hash function** maps items to buckets
- **Collisions**
  - # buckets < # possible pairs
  - A *collision* occurs when $h$ maps multiple items to the same bucket

Bucket 1 contains counts for \{c,j\} only, but bucket 2 contains counts for both \{b,c\} and \{c,m\}

Frequent pair \rightarrow Frequent bucket

Not frequent bucket \rightarrow Not frequent pair(s)

Frequent bucket \rightarrow \times \rightarrow Frequent pair(s)
PCY Algorithm – First Pass

FOR (each basket) :
    FOR (each item in the basket) :
        add 1 to item’s count;
    FOR (each pair of items) :
        hash the pair to a bucket;
        add 1 to the count for that bucket;

Few things to note:

- Pairs of items need to be generated from the input file; they are not present in the file
- We are not just interested in the presence of a pair, but we need to see whether it is present at least $s$ (support) times
Observations about Buckets

- **Observation:** If a bucket contains a frequent pair, then the bucket is surely frequent.
- However, even without any frequent pair, a bucket can still be frequent 😞
  - So, we cannot use the hash to eliminate any member (pair) of a “frequent” bucket.
- **But, for a bucket with total count less than** $s$, none of its pairs can be frequent 😊
  - Pairs that hash to this bucket can be eliminated as candidates (even if the pair consists of 2 frequent items).

- **Pass 2:**
  Only count pairs that hash to frequent buckets.
PCY Algorithm – Between Passes

- **Replace the buckets by a bit-vector:**
  - 1 means the bucket count exceeded the support $s$ (call it a frequent bucket); 0 means it did not

- 4-byte integer counts are replaced by bits, so the bit-vector requires 1/32 of memory

- Also, decide which items are frequent and list them for the second pass
PCY Algorithm – Pass 2

- Count all pairs \( \{i, j\} \) that meet the conditions for being a candidate pair:
  1. **A-priori**: Both \( i \) and \( j \) are frequent items
  2. **PCY**: The pair \( \{i, j\} \) hashes to a bucket whose bit in the bit vector is 1 (i.e., a frequent bucket)

- Both conditions are necessary for the pair to have a chance of being frequent
Main-Memory: Picture of PCY

- **Pass 1**
  - Hash table for pairs

- **Pass 2**
  - Counts of candidate pairs
  - Frequent items
  - Bitmap
  - Item counts

Main memory
More Extensions to A-Priori

- The MMDS book covers several other extensions beyond the PCY idea: “Multistage” and “Multihash”

- For reading on your own, Sect. 6.4 of MMDS

- **Recommended video** (starting about 10:10): https://www.youtube.com/watch?v=AGAkNiQnbjY
Frequent Itemsets in $\leq 2$ Passes (for pairs)

- Simple Algorithm
- Savasere-Omiecinski-Navathe (SON) Algorithm
- Toivonen’s Algorithm
Frequent Itemsets in $\leq 2$ Passes

- A-Priori, PCY, etc., take $k$ passes to find frequent itemsets of size $k$

- **Can we use fewer passes?**

- **Use 2 or fewer passes for all sizes, but may miss some frequent itemsets**
  - Random sampling
    - *Do not sneer*; “random sample” is often a cure for the problem of having too large a dataset.
  - SON (Savasere, Omiecinski, and Navathe)
  - Toivonen
Random Sampling (1)

- Take a random sample of the market baskets

- Run a-priori or one of its improvements like PCY in main memory
  - So we don’t pay for disk I/O each time we increase the size of itemsets
  - Reduce support threshold proportionally to match the sample size
    - Example: if your sample is 1/100 of the baskets, use \( s/100 \) as your support threshold instead of \( s \).
Random Sampling (2)

- **To avoid false positives:** Optionally, verify that the candidate pairs are truly frequent in the entire data set by a second pass

- **But you don’t catch sets frequent in the whole but not in the sample (false negative)**
  - Smaller threshold, e.g., $s/125$, helps catch more truly frequent itemsets ($s/125 < s/100$)
    - But requires more space
    - Note that the choice of 125 is arbitrary
SON Algorithm – (1)

- **SON Algorithm:** Repeatedly read small subsets of the baskets into main memory and run an in-memory algorithm to find all frequent itemsets
  - **Note:** we are not sampling, but processing the entire file in memory-sized chunks

- An itemset becomes a **candidate** if it is found to be frequent in any one or more subsets of the baskets.
SON Algorithm – (2)

- On a second pass, count all the candidate itemsets and determine which are frequent in the entire set.

- Key “monotonicity” idea: An itemset cannot be frequent in the entire set of baskets unless it is frequent in at least one subset.
Toivonen’s Algorithm: Intro

Pass 1:

- Start with a random sample, but lower the threshold slightly for the sample:
  - Example: if the sample is 1% of the baskets, use $s/125$ as the support threshold rather than $s/100$
- Find frequent itemsets in the sample
- Add to the itemsets that are frequent in the sample the **negative border** of these itemsets:
  - **Negative border**: An itemset is in the negative border if it is *not* frequent in the sample, but *all* its immediate subsets are
    - **Immediate subset** = “delete exactly one element”
Example: Negative Border

- \{A,B,C,D\} is in the negative border if and only if:
  1. It is not frequent in the sample, but
  2. All of \{A,B,C\}, \{B,C,D\}, \{A,C,D\}, and \{A,B,D\} are.
Toivonen’s Algorithm

- **Pass 1:**
  - Start with the random sample, but lower the threshold slightly for the subset
  - Add to the itemsets that are frequent in the sample the **negative border** of these itemsets

- **Pass 2:**
  - Count all candidate frequent itemsets from the first pass, and also count sets in their **negative border**

**Key:** If no itemset from the negative border turns out to be frequent, then we found *all* the frequent itemsets.
- What if we find that something in the negative border is frequent?
  - We must start over again with another sample!
  - Try to choose the support threshold so the probability of failure is low, while the number of itemsets checked on the second pass fits in main-memory.
We broke through the negative border. How far does the problem go?

... tripletons
doubletons
singletons

Frequent Itemsets from Sample
