CSE 550: Introduction to Computer Systems Research

Arvind Krishnamurthy
Course Information

- Instructor: Arvind Krishnamurthy
  - Interests: distributed systems, networks, operating systems
  - Email, office hours on the website
  - Also fine to just drop in!

- TA: Kaiyuan Zhang
Course Basics

- Quals course that covers foundational systems topics from:
  - Operating Systems, Networks, Distributed Systems, Databases
- No prerequisite
- Gateway course to CSE 551, 552, and 561 or a terminal course for students desiring breadth
Course Format

- Three components:
  - Reading papers and blog posts on papers, some experiments
  - Programming assignments in teams of two
  - Course project resulting in a project writeup
What is a computer system?

- Our focus is on software systems

- Software system achieves a specific external behavior
  - e.g., deliver videos, online social network, email, ML execution

- Comprises of many components
  - Components interact and cooperate to provide overall behavior
  - They typically have (well) specified interfaces
Thought Exercise

- Let us say that you want to build a gmail-like service
  - What are the key components in its design?
  - Pick one component and discuss what are the key issues/tradeoffs
  - Example: discuss how many datacenters do you need and where would you place them?
Why study systems now?

- Datacenter computing
  - scalable distributed systems
  - advancements in networking
- Internet-wide systems such as block-chains
- Systems and ML
Course Topics

- Concurrency
- Web Services
- Local Transactions
- Distributed Transactions
- Distributed clocks
- Consensus/RSM/BFT
- Virtualization

- File systems
- Large storage systems
- DHTs, Internet systems
- Big data/ML
- Networking (cong. control)
- Networking (routing)
- Experiences
Key Goals in Systems

- Correctness
- Availability/reliability
- Security
- Performance
What makes achieving these goals hard?

- System complexity:
  - Large # of components
  - Large # of connections
  - Imprecise description
  - Irregular interactions, irregular resource needs

- Technology rarely the limit!
  - Limit is usually the complexity, ability to reason, etc.
Example: EC2 Outage

- Background on EC2:
  - Multiple regions; multiple “availability zones” within each region
  - Each availability zone provides the Elastic Block Store (EBS)
  - EBS volumes are mountable on EC2 nodes
  - Replicated to deal with faults
  - EBS nodes use a “peer-to-peer” protocol to detect faults and replicate; blocks while trying to replicate
  - EBS nodes connected by a backup lower capacity network for providing reliable control
  - Control plane keeps track of volume locations; replicated/shared across the entire region
Outage

- Configuration change to upgrade a router
  - Normally shift traffic off to a full-capacity redundant router
  - Instead, mistakenly assigned to the backup router which overloaded

- EBS nodes weren’t able to contact each other, so declared failure and tried to provision extra copies
  - Exhausted space. Created a “re-mirroring” storm.
Outage (contd.)

- Created a huge load on the control plane
  - could not handle operations from other availability zones
  - Operators recognized the problem and disabled “re-mirroring” operations
- Caused further problems! No aggressive back-off
  - there was a race condition in EBS nodes in closing connections -- which caused them to actually fail
  - resulting in further re-mirroring
  - Operators finally disconnected the availability zone
What are the take-aways from this incident?
Unix Time Sharing System

- Classic system and paper: described almost entirely in 10 pages
- Key idea: elegant combination of a few concepts that fit together well
- Third system for time sharing:
  - First system was CTSS an unqualified success
  - Followed by Multics, which suffered from the second system effect
Unix

- Designed by Ritchie and Thompson
- Platform: PDP-11 computer; operational in 1971
- Written in C (instead of assembly -- 33% overhead)
- 2 man-years to write
- Defined an ecosystem — the Unix tools
  - Written collaboratively
  - Developers used/built the system for their own work
Unix Components

- File systems (ordinary files and device I/O)
- Process management
- Shell

Question: is there anything missing from the above list?
File System

- “Important job of Unix is to provide a file system”
- Three types of files:
  - Ordinary files: sequence of bytes (unstructured)
  - Directories (protected ordinary files)
  - Special files (I/O)
- Uniform I/O, naming, and protection model
  - directories (protected files), hierarchical, linking
Removable File System

- Tree structured
- "mount"-ed on an ordinary file
  - Associate a special device file with an ordinary file inside the tree structure
File System Implementation

- Table of i-nodes
- Path name scanning
- Mount table
- Buffered data
- Write-behind
Processes

- Text, data, and stack segments
  - Text is shared, the rest are process-specific
- Process swapping
- fork, exec: create new processes from same or different images
- Pipes for communicating between processes
- wait, exit: synchronization primitives
Shell

- Invoke programs: “cmd arg1 ... argn”
- Performs stdio and I/O redirection
- Filters & pipes
- Multi-tasking from a single shell
- Shell is just a program!
Questions

- What are the key design principles employed in Unix?
- What has changed and what hasn’t?
- What would you do differently for different settings (e.g., handheld devices)?
- How would you evaluate this paper now?
